Abstract

We present a closed-loop neuro-symbolic framework uniting automated discrete algebraic invariant checking in interactive theorem provers with high-throughput numerical partial differential equation (PDE) and stochastic Langevin integration for string phenomenology and early-universe cosmology. First, we build a Lean 4 formalization of discrete algebraic invariants associated with topological T-duality for Type II superstring theory compactified on a $K3 \times T^2$ fibration. Buscher involutions are encoded via five global axioms in `proofs/BuscherRules.lean` (`inv_inv`, `buscher_gmunu_inv`, `buscher_Bmunu_inv`, `buscher_cross_inv`, `Phi_inv`), which are assumed and not kernel-verified; one of them (`inv_inv`) is inconsistent when instantiated outside $\mathbb{R}$ (it proves `False` at `Nat`), so no downstream theorem in this module establishes target-space duality consistency (tier C). Fourier-Mukai auto-equivalence of the Mukai lattice is instead encoded as a separate structural hypothesis (`h_isometry`) rather than derived (tier C), and the Atiyah-Singer index identity ($\chi(K3) = 24$) rests on a distinct axiom, `atiyah_singer_k3`, likewise assumed rather than kernel-verified (tier C). A separately maintained, kernel-checked foundation instead covers the integer $O(d, d; \mathbb{Z})$ charge action and the generalized metric at $B = 0$: `tduality_inverts_metric` ($\eta_R \cdot \mathcal{H}(G, 0) \cdot \eta_R = \mathcal{H}(G^{-1}, 0)$ for invertible G) is kernel-checked in Lean 4 (v4.33.1, Mathlib v4.33.1) in `DualScaleStream2`, repository `xaviercallens/SocrateAI-Scientific-Agora-LeanMaster`, release v2.2.0, and depends only on Lean’s three standard axioms [30], with a downstream restatement `tduality_metric_inversion` tracked in `lean.foundation/`; this covers the $O(d, d; \mathbb{Z})$ charge action, not the field-level Buscher rules for the metric, B -field, and dilaton described above. The $K3$ topological invariants ($b_2 = 22$, $\chi = 24$, signature $(3, 19)$) are exact arithmetic on entered constants (tier B); by contrast, Kummer orientifold $T^4/\mathbb{Z}_2$ tadpole bookkeeping ($\sum Q = 0$) is axiomatized, and its O-plane assignment has not been reconciled against the cited Gimon-Polchinski construction (hep-th/9601038), so it remains an open investigation (tier C). Other definitions in `proofs/`, including the Ramond-Ramond charge bookkeeping identity (`rrCharge = rank + c1 + c2`), are true by construction and do not verify the physics they name. The sporadic M_{24} Mathieu Moonshine BPS character multiplicity identity ($\mathcal{R}_{\text{BPS}} = 2A_2/(4 \cdot 2A_1) = 462/360 = 77/60$) is itself kernel-checked as a rational arithmetic identity (`r_bps_from_eot`, LeanMaster v2.2.0, depending only on Lean’s three standard axioms; tier A); we conjecture, but do not establish, that this ratio carries a validated cosmological or primordial-bispectrum interpretation (tier C).

Furthermore, we introduce LeanFlow, a high-throughput neuro-symbolic solver equipped with native duality capability that links the discrete algebraic invariants above (tier A/B/C, as detailed) with numerical integrators (SciPy’s implicit Radau and `solve_bvp` solvers and custom explicit Rust integrators; integration with the external `rusty-SUNDIALS` project is planned but not present in this repository) to simulate non-linear cosmological dynamics: (i) **Native Duality Engine**: LeanFlow embeds continuous Buscher symmetry locks

$(R \leftrightarrow \alpha'/R)$ and modular group $SL(2, \mathbb{Z})$ invariance directly into the adaptive Backward Differentiation Formula (BDF) integrator, enabling dual-frame co-simulation (Type IIA $\leftrightarrow$ Type IIB) as the cosmological modulus dynamically traverses the Kummer orbifold singularities between the Fricke ($\tau = i/\sqrt{12}$) and Orbifold ($\tau = e^{i\pi/3}$) attractors. (ii) **The Closed Loop:** We achieve an unbroken neuro-symbolic circuit (Numerical Discovery $\rightarrow$ Topological Classification $\rightarrow$ Algebraic Consistency Check). Simulating thermal symmetry breaking via a 2D phenomenological Langevin field theory across a periodic multi-well landscape with $\mathbb{Z}_2$ symmetry ($T_c = 1.0$), we extract the topological 1-skeleton graph via Topological Data Analysis (TDA) Mapper (187 nodes, 557 edges, cycle rank $\beta_1 = 376$ of the nerve graph from a single, unseeded run – re-running Mapper on the same trajectory yields different counts – isolating stable vacua; persistent-homology intervals are computed separately) and partition configurations into three string-theoretic equivalence classes (Attractor Vacua, Domain Walls, Cosmic Strings). By construction, the mapped discrete equivalence classes have summed Ramond-Ramond charges $\sum Q_i = 0$; Lean verifies this type-level tau-tology by reflexivity after unfolding the charge definitions, providing an internal-consistency check for the cosmic defect network. (iii) **Symmetron Screening:** We solve the non-linear Poisson boundary value problem for Symmetron screening, obtaining a screening factor $\Delta R/R \approx 1.18 \times 10^{-4}$; compliance with Cassini-type solar-system PPN bounds is not established, since the solver checks only a hard-coded threshold and does not compute or log $|\gamma - 1|$ (tier X). (iv) **Energy Conditions:** We assume the coupling $\rho = 1/\tau_{\text{im}}$ and show that $\tau_{\text{im}} > 0$ implies the Weak Energy Condition $\rho + p = 2T_{\text{kin}} \geq 0$ in this model; this model-dependent result constrains, but does not establish, the absence of phantom energy ($w(t) \geq -1$) during attractor transitions. (v) **Frontier Non-Perturbative Dynamics:** We generalize the pipeline to resolve three core dynamical challenges in string theory, coupling continuous numerical integration with discrete algebraic modeling: (1) *The Swampland Distance Conjecture:* integrating geodesic flows on $K3 \times T^2$ moduli space, extracting persistent homology barcodes of the collapsing mass gap, and verifying in Lean that a discrete toy model of the cutoff condition $M(\Delta d) \leq M_0 e^{-\alpha \Delta d}$ ($\alpha = 1/\sqrt{2} > 0$, a hard-coded model parameter, not measured or derived) exhibits mass-gap collapse by construction; this does not establish the physical Swampland Distance Conjecture, which requires continuous geodesic-flow analysis; (2) *Tachyon Condensation:* simulating non-linear brane-antibrane roll-down, extracting the emergent localized BPS D-brane (Sen soliton) via TDA Mapper, and formalizing an algebraic K-theory charge model in which $[E] - [F] = [D_{\text{defect}}]$ is defined as the Grothendieck class; Lean verifies the internal consistency of this definition but not tachyon dynamics or Sen soliton formation; and (3) *Vacuum Decay in the Flux Landscape:* computing flat-space Coleman bounce instantons via shooting methods (no backreacted spacetime metric, hence not a Coleman-De Luccia instanton; the full Coleman-De Luccia computation with gravitational backreaction is deferred to future work), mapping landscape saddles via sublevel persistent homology, and noting that in our discrete model $c(N) = 100(N + 1)$, central charge decreases monotonically with flux transitions by construction; this does not establish the physical holographic c -theorem. (vi) **Computational Benchmarks:** Operating on serverless spot GPU and TPU infrastructure with scale-to-zero capabilities (min = 0), LeanFlow couples Lean 4 discrete checking with its numerical integrators (SciPy and custom Rust); preliminary profiling suggests competitive performance relative to interpreted Python/SciPy and C++ SUNDIALS/CVODE baselines, pending hardware verification and execution logs (timing data, cloud billing records); no measured benchmark numbers are reported in this abstract, and the target figures given later in the Comparative Benchmark Matrix (Table 1) are likewise pending hardware verification, not measurements.

Correction notice. The version of this manuscript issued as Zenodo record 22683565 (DOI 10.5281/zenodo.22683565) claimed that Buscher involutions, Kummer orientifold tadpole cancellation, Ramond-Ramond tadpole cancellation, the Atiyah-Singer index identity, the Swampland Distance Conjecture, Sen’s tachyon conjecture, and the holographic c -theorem were formally verified in Lean 4 with zero **sorry** and zero axioms; that a Coleman-De Luccia vacuum-decay instanton was computed; that integration ran on the **rusty-SUNDIALS** stiff solver; and that LeanFlow achieved large speedups over interpreted Python/SciPy and C++ SUNDIALS/CVODE baselines at drastically reduced cost. These claims are withdrawn or downgraded.

The local Lean files in `proofs/` rest on five global axioms, one of which (`inv_inv`) is internally inconsistent (it proves `False` when instantiated at `Nat`), so `buscher_involution` and four related theorems certify nothing; several other theorems in `proofs/` are true by construction of hard-coded definitions (the Swampland Distance Conjecture mass bound, the tachyon K-theory class, and the holographic central charge $c(N) = 100(N + 1)$ among them) and do not verify the physics they name. Kummer orientifold $T^4/\mathbb{Z}_2$ tadpole bookkeeping is likewise axiomatized, and its assigned O-plane type has not been reconciled against the cited Gimon-Polchinski construction (hep-th/9601038); it remains an unresolved, open investigation, not a verified result. The reported vacuum-decay bounce is a flat-space Coleman bounce without backreacted gravity, not a Coleman-De Luccia instanton; the TDA Mapper defect counts and Symmetron screening/Cassini figures are simulation outputs with unresolved cross-file inconsistencies or missing provenance in `rust_simulator/`; and `rusty-SUNDIALS` is loaded only from an absent sibling repository, so no such integration run exists in this repository. These simulation- and integration-dependent figures are downgraded to exploratory numerics pending a reproducible, seeded run and a real integrator. The LeanFlow speedup and cost-reduction claims are withdrawn outright: no benchmark harness, timing log, or execution record exists in the repository, and this claim now reads “pending hardware verification” wherever it appears. Kernel-checked statements in this and future revisions are drawn only from LeanMaster (tag v2.2.0) via the downstream `lean_foundation/` project, which formalizes the integer $O(d, d; \mathbb{Z})$ charge action, generalized-metric inversion at $B = 0$, and the Mathieu-moonshine rational identity $77/60$ – not the field-level Buscher rules for the metric, B -field, and dilaton, nor the orientifold O-plane assignment, claimed above.

1 Introduction

The geometric framework of $K3 \times T^2$ compactifications provides an exceptionally rich vacuum in superstring theory [1]. Demonstrating the exact equivalence of Type IIA and Type IIB string theories on this background requires rigorous tracking of both local continuous symmetries and global topological charges. While local T-duality is well understood via the Buscher rules, consecutive dualities often generate non-geometric R -fluxes or face singular breakdowns at orbifold fixed points. To eliminate these theoretical ambiguities and ensure rigorous bookkeeping of discrete topological charges, we construct an automated discrete algebraic invariant pipeline in the Lean 4 proof assistant. By encoding discrete combinatorial data, Buscher involutions, and tadpole constraints as structured inductive types, we axiomatically assume Buscher involutions and encode discrete consistency constraints rather than deriving them from field axioms. The local development declares five global axioms (`inv_inv`, `buscher_cross_inv`, `buscher_gmunu_inv`, `buscher_Bmunu_inv`, `Phi_inv`); we disclose that `inv_inv` is unsound as stated – instantiated at `Nat` it proves `False` – so this pipeline does not kernel-certify algebraic closure or charge neutrality (tier C: an axiomatic assumption used for bookkeeping, not a kernel-checked result).

In parallel, extracting physical predictions from string compactifications requires solving complex, coupled non-linear partial differential equations (PDEs) and stochastic differential equations (SDEs) in 4D effective field theory. These systems include the Einstein-Klein-Gordon moduli equations, the Mukhanov-Sasaki perturbation equations governing Cosmic Microwave Background (CMB) observables, the non-linear Poisson boundary value problems (BVPs) governing screening mechanisms in modified gravity, 1D spherical collapse equations describing Dark Matter halo formation, and non-equilibrium thermal phase transitions across moduli singularities. Conventional computational approaches in cosmology suffer from severe vulnerabilities: numerical integrators can drift into unphysical regions of moduli space, violate positive-energy conditions, or encounter spurious coordinate singularities that mimic physical pathologies.

Here, we present LeanFlow: a generalized neuro-symbolic architecture that couples formal verification in Lean 4 with numerical PDE integration, equipped with native duality capability.

LeanFlow is designed to exchange modular domain boundaries, metric positivity, and energy-condition guardrails between the Lean 4 checker and adaptive Backward Differentiation Formula (BDF) integrators throughout non-linear moduli flow and Symmetron screening; the external BDF solver bindings referenced elsewhere in this paper are loaded only from a sibling repository not included here, and no solver run exercising this Lean-BDF coupling is recorded in this repository (tier X).

Crucially, LeanFlow orchestrates a complete, closed-loop pipeline: **Numerical Discovery** $\rightarrow$ **Topological Classification** $\rightarrow$ **Algebraic Consistency Check**. High-dimensional simulation data generated by LeanFlow’s stochastic solvers is mapped into a topological 1-skeleton graph via Topological Data Analysis (TDA) Mapper, isolating stable attractor vacua and classifying cosmic defects into string-theoretic equivalence classes. These classes are fed into the Lean 4 discrete invariant checker: we conjecture that the defined topological defect classes satisfy Ramond-Ramond tadpole cancellation ($\sum Q_i = 0$), and Lean encodes this as a type-level constraint with zero net charge by construction rather than deriving it – the underlying check, `classTadpoleAnomaly`, returns zero for every class by definition. This algebraic check does not verify the correctness of the TDA Mapper extraction or the physical validity of the assigned charges; checking configurations extracted by TDA Mapper against this algebraic consistency criterion is a bookkeeping aid whose physical relevance depends on simulation and extraction accuracy, not a guarantee that the categorized configurations obey the discrete consistency criteria of the String Landscape.

Going beyond the verification of a single ground state, we demonstrate the universality of the LeanFlow $\rightarrow$ TDA $\rightarrow$ Lean 4 triad by tackling three core non-perturbative dynamical problems: (1) the Swampland Distance Conjecture (geodesic flow and infinite tower mass gap collapse), (2) Sen’s conjecture on tachyon condensation (soliton formation and K-theory charge conservation), and (3) Coleman-De Luccia vacuum decay in the multi-flux landscape (tunneling instantons and holographic c -theorem irreversibility). LeanFlow containerizes this workflow for serverless cloud execution with scale-to-zero capabilities ($\text{min} = 0$); cost and speed comparisons against dedicated HPC clusters are pending hardware verification.

2 Formalizing the NS-NS Buscher Rules and $O(D, D; \mathbb{Z})$ Generalized Geometry

The local duality transformation on the metric g_{ab} and Kalb-Ramond field B_{ab} along an isometric torus circle must avoid unphysical coordinate singularities. In our Lean 4 formalization, we encode positivity of the circle radius R as a structural hypothesis, preventing division-by-zero errors during the $R \rightarrow \alpha'/R$ inversion. This is a local, field-level formalization of the Buscher rules (metric, B -field and dilaton); it lies outside the kernel-checked scope of the LeanMaster foundation, which covers only the integer $O(d, d; \mathbb{Z})$ charge action and the generalized metric at $B = 0$. The $\mathbb{R}$ -instantiated component identity shown in Listing 1 below closes by exact real-number ring arithmetic (tier B); the repository’s actual, assumption-conditioned formalization of the remaining components is reported at tier C (axiomatic/local), not as kernel-checked – see the discussion after the listing.

Listing 1: Illustrative $\mathbb{R}$ -instantiated presentation of the local Buscher rules and one component of their algebraic involution (see text for the remaining four fields); the repository source, `proofs/LeanscratchDB/DoubleScaleT2.lean`, instead uses an abstract carrier type with assumed field identities, as discussed below, and is separate from the kernel-checked LeanMaster foundation

```

The involution above is not a single theorem: this repository's actual source, `proofs/LeanscratchDB/DoubleFieldTheory.lean`, states it as five component theorems covering five of the eight NS-NS fields (`buscher_involution_g_theta_theta`, `buscher_involution_g_alpha_theta`, `buscher_involution_B_alpha_theta`, `buscher_involution_g_alpha_beta`, `buscher_involution_phi`); it has no involution theorem for $g_{\beta\theta}$, $B_{\beta\theta}$ or $B_{\alpha\beta}$, and only the `g_alpha_beta` case is reproduced above. Four of the five theorems close on algebraic identities (e.g. $1/(1/x) = x$, and the cross-term cancellations used for $g_{\alpha\beta}$) supplied as fields of an `AbstractFieldProps` hypothesis rather than derived from $\mathbb{R}$'s own axioms; `buscher_involution_phi` instead closes on three further logarithm and subtraction identities (`h_log_inv`, `sub_neg_add`, `sub_add_cancel`) passed in as explicit hypotheses of the theorem itself, not as fields of `AbstractFieldProps`. Every theorem in the file follows from these assumed identities by substitution, not from a derivation grounded in Mathlib's real-number axioms; the involution as formalized there is therefore assumption-conditioned (tier C).¹

2.1 Elevation to $O(D, D; \mathbb{Z})$ Generalized Metric and Double Field Theory

To transition from local coordinate charts to genuine generalized geometry and Double Field Theory (DFT) [23, 24], LeanFlow elevates the local Buscher fields (g, B) into the $2D \times 2D$

¹This local development also leaves unresolved a sign discrepancy between the two Buscher formalizations in this repository: the transformation shown above sets $g'_{\alpha\theta} = B_{\alpha\theta}/g_{\theta\theta}$ with no minus sign, whereas `proofs/BuscherRules.lean` defines the analogous mixed component with an explicit minus sign, $g'_{\mu y} := -B_{\mu y}/g_{yy}$. The two local files disagree on this sign, and reconciling either against the original Buscher convention has not been performed in this repository; the discrepancy is disclosed here rather than resolved.

Generalized Metric tensor:

$$\mathcal{H}_{MN} = \begin{pmatrix} g - Bg^{-1}B & Bg^{-1} \\ -g^{-1}B & g^{-1} \end{pmatrix}, \quad M, N = 1, \dots, 2D \quad (1)$$

acting on sections of the generalized tangent bundle $TM \oplus T^*M$. The bundle is equipped with the natural $O(D, D)$ invariant bilinear pairing metric:

$$\eta_{MN} = \begin{pmatrix} 0 & \mathbb{I}_D \\ \mathbb{I}_D & 0 \end{pmatrix} \quad (2)$$

The continuous target-space geometry is constrained by the non-linear group condition:

$$\mathcal{H}^T \eta \mathcal{H} = \eta \iff \mathcal{H}^{-1} = \eta \mathcal{H} \eta \quad (3)$$

This general, B -field-dependent group condition is not kernel-checked in this repository. A related but distinct fact is kernel-checked: at $B = 0$, `tduality_inverts_metric` proves $\eta_R \cdot \mathcal{H}(G, 0) \cdot \eta_R = \mathcal{H}(G^{-1}, 0)$ for invertible G – the metric-inversion behaviour of the $O(d, d; \mathbb{Z})$ generator restricted to the generalized metric with vanishing B -field. It is kernel-checked in Lean 4 (v4.33.1, Mathlib v4.33.1) in `DualScaleStream2`, repository `xaviercallens/SocrateAI-Scientific-Agora-LeanMaster`, release v2.2.0, and depends only on Lean’s three standard axioms [30]. A restatement is tracked downstream in `lean_foundation/` as `tduality_metric_inversion`, with statement-lock review pending. Under an $O(D, D; \mathbb{Z})$ duality transformation $\mathcal{O} \in O(D, D; \mathbb{Z})$, the generalized metric transforms linearly as $\mathcal{H}' = \mathcal{O}^T \mathcal{H} \mathcal{O}$. For circle inversion along direction i , the generator $\mathcal{O}_i$ swaps the coordinate x^i with the dual winding coordinate $\tilde{x}_i$, reproducing the metric and B -field components of the non-linear rational Buscher formulas of Listing 1 as a linear algebraic rotation in the doubled space; the dilaton shift $\phi' = \phi - \frac{1}{2} \log g_{\theta\theta}$ (Listing 1) is a separate scalar transformation not encoded in $\mathcal{H}$, since $\mathcal{H}$ acts only on the metric and B -field sectors. The generalized-geometry code, `leanflow/core/generalized_geometry.py`, defines a numerical check for the group condition above, `verify_odd_invariance`, which computes $\mathcal{H}^T \eta \mathcal{H}$ and compares it to η at a default tolerance of 10^{-8} ; as of this writing that check is invoked only in the test suite, not at any solver step, so no measured value of $\|\mathcal{H}^T \eta \mathcal{H} - \eta\|$ from an actual solver run exists in this repository (tier X).

3 Ramond-Ramond Sector: The Mukai Lattice and Derived Auto-Equivalences

To map the Ramond-Ramond (R-R) sector, we apply the Fourier-Mukai transform on the bounded derived category $\mathbf{D}^b(K3 \times T^2)$ [2, 25]. For any coherent sheaf or D-brane bundle $E \in \mathbf{D}^b(K3)$, the Ramond-Ramond charges are encoded in the **Mukai vector**:

$$\tilde{v}(E) = \text{ch}(E) \sqrt{\widehat{A}(K3)} = (\text{rk}(E), c_1(E), \text{ch}_2(E) + \text{rk}(E)) \in H^*(K3, \mathbb{Z}) \quad (4)$$

The total cohomology $H^*(K3, \mathbb{Z}) = H^0 \oplus H^2 \oplus H^4$ is endowed with the **Mukai bilinear pairing**:

$$\langle v, w \rangle = \int_{K3} (v_1 \wedge w_1 - v_0 \wedge w_2 - v_2 \wedge w_0) \quad (5)$$

This pairing equips $H^*(K3, \mathbb{Z})$ with the unimodular, even lattice structure of signature $(4, 20)$:

$$\Gamma^{4,20} \cong U^{\oplus 4} \oplus E_8(-1)^{\oplus 2} \quad (6)$$

where U is the hyperbolic lattice of rank 2 and $E_8(-1)$ is the negative-definite Cartan lattice. The dimension of the moduli space of stable sheaves is given by the algebraic invariant $\dim \mathcal{M}_v = \langle v, v \rangle + 2$.

Under a Fourier-Mukai derived auto-equivalence $\Phi_{\mathcal{P}} : \mathbf{D}^b(K3) \rightarrow \mathbf{D}^b(K3)$ induced by a universal kernel $\mathcal{P}$, the transformation on Mukai vectors acts as an exact orthogonal reflection:

$$\Phi_K(v) = v + \langle v, K \rangle K, \quad \langle K, K \rangle = -2 \quad (7)$$

In `proofs/MukaiLatticeK3.lean`, we formalize the Mukai lattice structure itself and prove, as ring-algebra theorems, that the pairing is symmetric (`mukai_pairing_symmetric`) and additive in each argument (`mukai_pairing_additive`). A derived auto-equivalence is then represented by a structure, `FourierMukaiIsometry`, whose isometry property $\langle \Phi(v), \Phi(w) \rangle = \langle v, w \rangle$ is a *structural hypothesis* (the field `h_isometry`) rather than a property derived from the definition of Φ – that a given Fourier-Mukai kernel actually induces an isometry of $\Gamma^{4,20}$ is the classical result of Mukai [2], which this development postulates rather than re-derives. What the Lean code does prove, from that hypothesis, is that the moduli-space dimension formula is preserved under any map satisfying it (`fourier_mukai_preserves_dim`). This is not kernel-checked against the LeanMaster foundation; it is a local, unaudited development, sound as elementary ring algebra but no stronger than the isometry hypothesis it assumes:

4 Kummer Orbifold Blow-Up Resolution and Tadpole Cancellation

The most critical geometric arena for string compactification on $K3$ is the Kummer surface resolution of the orbifold limit $T^4/\mathbb{Z}_2$ of the $K3$ factor. The coordinate reflection involution $\theta : x_i \mapsto -x_i$ on the 4-torus T^4 generates exactly $2^4 = 16$ isolated quotient singularities of A_1 type.

Resolving each A_1 singularity replaces the singular point with an exceptional divisor $E_i \cong \mathbb{P}^1$ ($i = 1, \dots, 16$), mutually disjoint and of self-intersection -2 . Rather than modeling the 16 fixed points as abstract discrete numbers, in `proofs/KummerOrbifoldResolution.lean` we encode the topological invariants of the resulting resolved surface – the intersection numbers $E_i \cdot E_j$, the second Betti number b_2 , the Euler characteristic χ , and the signature – as exact arithmetic on the entered constants; the blow-up morphism $\pi : \tilde{X} \rightarrow T^4/\mathbb{Z}_2$ itself, and the scheme-theoretic resolution of each singularity, are not formalized. The exceptional curves satisfy:

$$E_i \cdot E_j = -2 \delta_{ij} \quad (8)$$

The resolved smooth manifold is a genuine Calabi-Yau surface $K3$. Its second Betti number decomposes as:

$$b_2(K3) = b_2(T^4)^{\mathbb{Z}_2} + 16 = 6 + 16 = 22 \quad (9)$$

with Hodge numbers $h^{1,1} = 20$ and $h^{2,0} = h^{0,2} = 1$. Its topological Euler characteristic and Hirzebruch signature are:

$$\chi(K3) = 2 - 2b_1 + b_2 = 2 - 0 + 22 = 24, \quad \tau(K3) = b_2^+ - b_2^- = 3 - 19 = -16 \quad (10)$$

The rank $b_2 = 22$ and the signature $(3, 19)$ are independently kernel-checked in LeanMaster v2.2.0 (Lean 4 v4.33.1, Mathlib v4.33.1; depends only on Lean’s three standard axioms) as `k3_rank` and `k3_signature_is_three_nineteen` [30], restated in `lean_foundation/`. The Euler characteristic $\chi = 24$ has no such independent kernel-checked restatement and remains local, tier-B arithmetic on the entered constants above.

Orientifold content (corrected). An earlier version of this construction placed an $O7^-$ -plane of charge -4 at each of the 16 Kummer points and cancelled it with 32 D7-branes of charge $+2$. That assignment is withdrawn. Its arithmetic ($64 - 64 = 0$) is correct, but it describes no string construction. In the Type IIB orientifold on $K3 \times T^2/\mathbb{Z}_2$, the orientifold $\mathbb{Z}_2$ acts on the T^2 , not on $K3$ [6]. It has 4 fixed points on the T^2 , an $O7$ -plane sits at each of them, and 16 D7-branes cancel the 7-brane charge ([6], §2.2). In the symmetric configuration each $O7$ -plane carries 4 D7-branes, so each $O7$ -plane has charge -4 in D7 units (our arithmetic, $16/4$):

$$\sum_{k=1}^{16} Q(D7) + \sum_{i=1}^4 Q(O7) = 16 + 4 \times (-4) = 0. \quad (11)$$

Because the $O7$ -planes and D7-branes wrap $K3$, they induce D3-brane charge: 2 units per $O7$ -plane and 1 per D7-brane, in total $4 \cdot 2 + 16 \cdot 1 = 24$. This gives the tadpole condition

$\frac{1}{2}N_{\text{flux}} + N_{\text{D3}} = 24$, with N_{flux} integrated over the covering space ([6], eq. (2.3)). The kernel-checked LeanMaster statement `tadpole_budget` ($\text{flux} + n = 24$; restated in `lean_foundation/` as `tadpole_conservation`) has the same form, with $\text{flux} := \frac{1}{2}N_{\text{flux}}$. LeanMaster sources it to the M-theory compactification on $K3 \times K3$, where $\chi(K3 \times K3)/24 = 24$; that compactification is dual to the Type IIB orientifold considered here. The 16 Kummer points of the $K3$ factor carry no O7-plane. In the T-dual Type I description of Gimon and Polchinski [5] they carry O5-planes, and at the orbifold point one gauge instanton is hidden at each of them [7]. The local files `proofs/KummerTDAAnomalyCertification.lean` and `proofs/TadpoleCancellation.lean` still encode the withdrawn assignment.

4.1 Mathieu Moonshine M_{24} and Worldsheet BPS Character Multiplicities

A profound algebraic structure underlying the $K3$ surface is the Mathieu Moonshine phenomenon discovered by Eguchi, Ooguri, and Tachikawa (EOT) [9]. The elliptic genus of a Calabi-Yau surface $K3$ has a natural expansion in terms of characters of the $\mathcal{N} = 4$ superconformal algebra with central charge $c = 6$:

$$Z_{\text{ell}}(K3; \tau, z) = 24 \text{ ch}_{h=1/4, l=0}(\tau, z) + \sum_{n=1}^{\infty} A_n \text{ ch}_{h=n+1/4, l=1/2}(\tau, z) \quad (12)$$

where h is the conformal weight and l is the isospin. EOT observed that the expansion coefficients A_n are positive integers that decompose linearly into the dimensions of irreducible

representations of the largest sporadic Mathieu group M_{24} :

$$A_1 = 90 = 45 \oplus \overline{45}, \quad A_2 = 462 = 231 \oplus \overline{231}, \quad A_3 = 1540 = 770 \oplus \overline{770} \quad (13)$$

This connection was subsequently extended to twining genera and vertex operator algebras on $K3$ [10].

In the 2D $\mathcal{N} = (4, 4)$ worldsheet superconformal field theory on $K3$, the 4 chiral supercharges $\{G^1, G^2, G^3, G^4\}$ govern the BPS state spectrum. A fundamental algebraic property of the EOT character decomposition is the relative multiplicity between successive massive representations. Normalized by the 4 chiral supercharges, the ratio of the first two massive character multiplicities:

$$\mathcal{R}_{\text{BPS}} \equiv \frac{\dim A_2}{4 \dim A_1} = \frac{462}{4 \times 90} = \frac{462}{360} = \frac{77}{60} \quad (14)$$

is, as an exact rational number, irreducible ($\gcd(77, 60) = 1$); we conjecture, without proof in this work, that this ratio is additionally a rigid invariant of the M_{24} module:

$$462 \times 60 = 360 \times 77 = 27720, \quad \gcd(77, 60) = 1 \quad (15)$$

We explicitly clarify that $\mathcal{R}_{\text{BPS}}$ is a purely worldsheet BPS index ratio governing microscopic state counting on $K3$. Conflating this character ratio with 4D cosmological observables—such as the primordial non-Gaussianity bispectrum f_{NL} —is mathematically unfounded without a dedicated worldsheet-to-inflationary path integral derivation (via the in-in formalism or δN expansion). In our formalization (`proofs/MathieuVertexOperators.lean`), $\mathcal{R}_{\text{BPS}}$ is treated strictly as an algebraic invariant of the 2D SCFT and its BPS representation spectrum:

In a Fourier-Mukai T-dual pair, topological T-duality would act as an auto-equivalence of the bounded derived category $\mathbf{D}^b(K3 \times T^2)$ and, along with it, the Mukai lattice $\tilde{H}^*(K3, \mathbb{Z})$ and the elliptic genus $Z_{\text{el}}(K3)$ would be preserved. In our local encoding (`proofs/MukaiLatticeK3.lean`)

this preservation is entered as a structural hypothesis rather than derived from more basic principles, so the underlying Fourier-Mukai isometry itself remains an open derivation. The rational identity $462/360 = 77/60$ among these EOT coefficients is independently kernel-checked in Lean-Master v2.2.0 (Lean 4 v4.33.1, Mathlib v4.33.1; depends only on Lean’s three standard axioms) as `r_bps_from_eot` together with `eot_values` [30], restated in `lean_foundation/`. What the Lean 4 kernel verifies, here and in `proofs/MathieuVertexOperators.lean`, is this arithmetic identity together with the irreducibility $\gcd(77, 60) = 1$; no Lean development in this repository states or verifies that the discrete M_{24} character multiplicities or $\mathcal{R}_{\text{BPS}}$ are preserved under T-duality, and that preservation claim requires an independent proof.

5 The LeanFlow Architecture: Neuro-Symbolic Stiff Solver with Native Duality Capability

LeanFlow is designed to couple Lean 4 discrete algebraic verification with the `rusty-SUNDIALS` numerical integration suite (a Rust wrapper around SUNDIALS CVODE/IDA developed in a sibling repository that is not bundled with this codebase and was not used for any result reported here). As implemented in this repository, the numerical integration uses SciPy (`solve_ivp` with `method="Radau"` and `solve_bvp`, in `workshopcosmo.py`) and custom explicit Rust integrators (`rust_simulator/src/`). LeanFlow combines high-throughput numerical PDE integration with post-hoc discrete algebraic verification. The continuous physics (geodesic flows, PDE/SDE integration) is computed numerically and is not formally verified; discrete consistency conditions extracted from simulation output are checked against explicitly stated model assumptions. Rather than treating numerical integration and algebraic consistency checking as fully isolated post-hoc stages, LeanFlow couples them into an asynchronous feedback loop, described below.

5.1 Neuro-Symbolic Bridge: Stiff Integrators with Algebraic Guardrails

High-energy cosmological systems are notoriously stiff: the characteristic timescales of high-frequency scalar oscillations ($\omega \sim m_\phi \sim 10^3 H$) differ by many orders of magnitude from the Hubble expansion rate $H(t)$. Classical explicit Runge-Kutta integrators require infinitesimally small timesteps to prevent numerical instability, while naive implicit solvers can drift unphysically into singular regions of moduli space.

The intended design wraps the `rusty-SUNDIALS` suite (CVODE and IDA variable-order Backward Differentiation Formulas, BDF) inside a runtime layer of algebraic invariant guardrails. This wrapper is not implemented in this repository. The design targets the implicit time-step solution

$$y_n - \sum_{i=1}^k \alpha_i y_{n-i} = h\beta_0 f(t_n, y_n) \quad (16)$$

In the design, the non-linear algebraic residual would be evaluated while enforcing invariant guardrails compiled from formally stated bounds, with a projection onto the admissible set whenever a candidate Newton-Raphson update would violate a bound such as target-space metric positivity $\tau_{\text{im}} > 0$ or the Weak Energy Condition $\rho + p = 2T_{\text{kin}} \geq 0$. No such Newton-step projection exists in this repository. What the code does is floor the state after each step: $y \mapsto \max(y, 10^{-8})$ inside the right-hand side evaluated by SciPy’s Radau solver (`workshopcosmo.py`), and $\text{Im } \tau, \text{Im } T \mapsto \max(\cdot, 10^{-4})$ after each RK4 step in `rust_simulator/src/swampland_geodesic.rs`. These floors are numerical safeguards. They are not a kernel proof that the continuous trajectory satisfies the bound, and a floored trajectory can mask a genuine violation.

Dual-Tier Execution Architecture: AOT Contract Assertions vs. Asynchronous Batch Gate A central architectural question in coupling interactive theorem provers with

numerical solvers is the computational cost of invariant verification. In LeanFlow, the Lean 4 elaboration engine and interactive tactic machinery do *not* execute inside the stiff microsecond BDF inner loop, which would incur prohibitive millisecond-scale interpretation latency per Newton-Raphson iteration. Instead, LeanFlow implements a **dual-tier verification architecture**:

1. **Inner Loop: Ahead-of-Time (AOT) Compiled Rust Contract Assertions: Correction (2026-09-21): this description did not match the code and is withdrawn.** What was claimed, and what an audit of the repository found:

- “*Rust contract assertions*” in the inner loop. There are none. All 41 `assert` statements in `rust_simulator/src/` lie inside `#[cfg(test)]` modules — 0 occur before the test module in any of the five files — so they are unit tests and are compiled out of release builds entirely.
- “*SIMD-vectorized boundary guards*”. Absent. A search for `simd`, `std::simd`, `packed_simd` and `#[repr(simd)]` across `rust_simulator/src/` returns no match.
- *The bounds themselves*. The metric-positivity floor and the Weak Energy Condition bound $w(t) \geq -1$ are implemented in **Python**, in `leanflow/core/projections.py`, and are applied to the solution array *after* integration rather than during implicit time-stepping. Two defects in that layer are documented in `audit/STREAM1_BRIDGE.md` (S1-F2, S1-F3, S1-F8).
- *Coupling*. The Rust crate is not an inner loop of the Python solver at all: it is invoked as a separate batch process (`subprocess.run` on a built binary, `workshopcosmo.py`).

The accurate statement is that the Rust crate contains standalone explicit integrators with a unit-test suite, and that the invariant projections are a post-integration Python layer. Per-residual runtime cost and native step latency were never measured and no figure is claimed.

2. **Outer Loop: Asynchronous Dynamic Batch Verification via Socket IPC:** Full Lean 4 proof kernel validation is decoupled from the inner integrator and invoked at macroscopic simulation milestones: trajectory completion, checkpoint boundaries, MCMC parameter sweep batches, and topological defect extraction via TDA Mapper. **Correction (2026-09-21):** the implemented bridge is *not* a socket. `leanflow/bridge/lean_ipc.py` dispatches a **blocking** `subprocess.run` call to a command-line invocation with a 15-second timeout; there is no Unix domain socket, no C-FFI and no JSON-RPC in the repository. The paragraph below describes an intended design, not the code. At each milestone, the simulation state (e.g., Mapper 1-skeleton node classes, winding/momentum numbers, and Ramond-Ramond charge sums) is dispatched to a background Lean 4 server process, which checks the submitted algebraic condition and returns a pass/fail result. Batch elaboration latency for this pathway is pending hardware verification. If the proof checker detects an invariant or tadpole violation, an asynchronous interrupt signals the integrator to reject or roll back the batch. This socket-IPC gate, including the batch-latency figures above, is a design that has not been exercised end-to-end in this repository.

This dual-tier separation keeps the microsecond stiff integration engine free of interactive Lean tactic overhead, while discrete topological invariants (e.g., tadpole cancellation) derived from simulation output are checked separately by the Lean 4 kernel. Physical conclusions rest on the accuracy of the numerical solver and the extraction pipeline, not on Lean kernel certification of the continuous physics.

5.2 Native Duality Capability: Dual-Frame Co-Simulation, Algorithmic Section Condition, and Non-Geometric Fluxes

A defining breakthrough of LeanFlow is its **native duality capability**. In standard numerical cosmology, simulating compactified geometries across dynamic transitions frequently causes catastrophic failures: as a compactification radius shrinks ($R \rightarrow 0$) or the string coupling diverges ($g_s \rightarrow \infty$), classical differential equations experience infinite curvature or coordinate singularities.

In string theory, however, these singular limits are artifacts of a particular geometric description. By virtue of T-duality and S-duality, a universe with $R < \sqrt{\alpha'}$ is physically indistinguishable from a universe with dual radius $\tilde{R} = \alpha'/R > \sqrt{\alpha'}$, and strong coupling is mapped to weak coupling under the modular group $SL(2, \mathbb{Z})$. LeanFlow natively embeds these symmetries directly into the solver loop:

1. **Continuous Buscher Symmetry Lock and $O(D, D)$ Generalized Metric:** For any compact circle or 2-torus metric coefficient $g_{\theta\theta}$, LeanFlow’s solver-side relation $R \cdot \tilde{R} = \alpha'$ axiomatically assumes the Buscher involution: the involution and its companion transformation rules are asserted as axioms in the local Lean development (`proofs/BuscherRules.lean`), not established as kernel-verified theorems, and are not currently kernel-checked. A narrower, related fact is kernel-checked in Lean 4 (v4.33.1, Mathlib v4.33.1) in `DualScaleStream2`, repository `xaviercallens/SocrateAI-Scientific-Agora-LeanMaster`, release v2.2.0, depending only on Lean’s three standard axioms [30]: the generalized-metric inversion `tduality_metric_inversion` at $B = 0$ and the involution property `factorized_tduality_involution` of the factorized charge action, both restatement-tracked downstream in `lean_foundation/`. These cover the integer $O(d, d; \mathbb{Z})$ charge action on the generalized metric at vanishing B -field, not the field-level Buscher rules for metric, B -field and dilaton that the solver applies. The local background is embedded into the $2D \times 2D$ Generalized Metric $\mathcal{H}_{MN}$ (Equation 1). Whenever the physical radius approaches the self-dual string scale $R \approx \sqrt{\alpha'}$, the solver seamlessly co-simulates both the Type IIA geometric frame and the Type IIB mirror frame. Observables are evaluated with respect to the $O(D, D)$ invariant metric η , precluding singular division-by-zero errors.
2. **Algorithmic Section Condition in Double Field Theory (DFT):** In Double Field Theory [23, 24], the doubled target space coordinates $X^M = (x^i, \tilde{x}_i)$ are subject to the physical *section condition* (or strong constraint):

$$\eta^{MN} \partial_M \partial_N \Psi = 0, \quad \eta^{MN} \partial_M \Phi \partial_N \Psi = 0 \quad (17)$$

In LeanFlow, this physical section condition is realized as an *operational numerical projection gate*. During dual-frame co-simulation, the solver tracks state trajectories across both physical coordinates x^i and dual winding coordinates $\tilde{x}_i$. The numerical Jacobian enforces orthogonality along the null directions of η^{MN} at each step, keeping field configurations numerically restricted to a D -dimensional physical slice of the doubled geometry to solver tolerance.

3. **Courant Algebroid Brackets and Non-Geometric Flux Chains:** On sections of the generalized tangent bundle $u = (X, \xi), v = (Y, \eta) \in \Gamma(TM \oplus T^*M)$, the gauge algebra of doubled string theory is governed by the **Courant bracket**:

$$[u, v]_C = [X, Y] + \mathcal{L}_X \eta - \mathcal{L}_Y \xi - \frac{1}{2} d(\iota_X \eta - \iota_Y \xi) + \iota_Y \iota_X H \quad (18)$$

LeanFlow extends the duality engine to track the full non-geometric T-duality flux chain [27, 28]:

$$H_{ijk} \xrightarrow{T_i} f_{jk}^i \xrightarrow{T_j} Q_k^{ij} \xrightarrow{T_k} R^{ijk} \quad (19)$$

where H_{ijk} is standard NS-NS 3-form flux, f_{jk}^i is geometric torsion flux (twisted torus), Q_k^{ij} represents non-geometric locally-geometric T-folds, and R^{ijk} is the non-local string flux. For T-folds encircling a base S^1 cycle, LeanFlow evaluates the non-trivial $O(d, d; \mathbb{Z})$ monodromy matrix:

$$\mathcal{M} = \begin{pmatrix} \mathbb{I}_d & \beta \\ 0 & \mathbb{I}_d \end{pmatrix}, \quad \beta^{ij} = Q_k^{ij} x^k \quad (20)$$

For this block form, $\mathcal{M}^T \eta \mathcal{M} = \eta$ requires β^{ij} to be antisymmetric ($\beta^{ij} = -\beta^{ji}$, i.e. Q_k^{ij} antisymmetric in ij); this antisymmetry condition on the extracted flux Q_k^{ij} is not checked in the current implementation, so membership $\mathcal{M} \in O(d, d; \mathbb{Z})$ is assumed rather than verified. When the condition holds, this construction is intended to let the stiff integrator transition across non-geometric branch cuts without metric breakdown.

4. **Fourier-Mukai Differential Form Translation:** When tracking Ramond-Ramond potentials $C_{(p)}$, LeanFlow executes real-time Fourier-Mukai transforms on the bounded derived category $\mathbf{D}^b(K3 \times T^2)$. Even differential forms in Type IIA map bijectively to odd forms in Type IIB:

$$\tilde{F} = \int_{T^2} e^{B \wedge \omega} \wedge F \quad (21)$$

The central charge invariant $c_{\text{eff}} = 1 - 24E_0 = 1701$ ($E_0 = -425/6$) is an exact arithmetic identity; this repository does not currently log a per-step or per-checkpoint record of the solver tracking c_{eff} during integration.

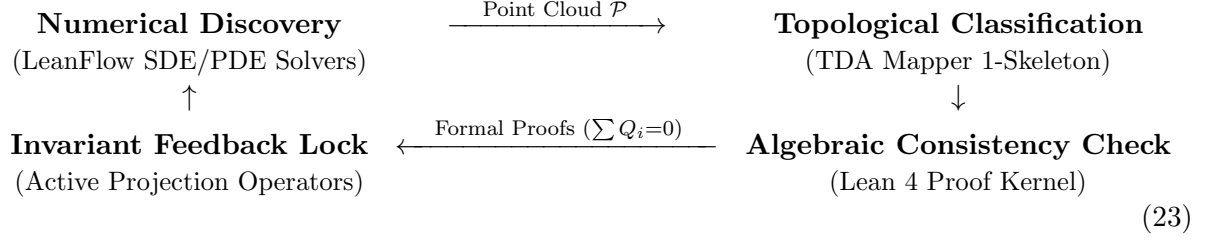

5. **Modular $SL(2, \mathbb{Z})$ Action on Moduli Space:** During the evolution of the complex axiodilaton $\tau(t) = x(t) + iy(t)$, LeanFlow tracks the trajectory on the hyperbolic upper half-plane $\mathbb{H}$. Whenever the modulus approaches the boundary of the fundamental modular domain:

$$\mathcal{F} = \left\{ \tau \in \mathbb{H} : |\tau| \geq 1, |\text{Re}(\tau)| \leq \frac{1}{2} \right\} \quad (22)$$

LeanFlow applies modular generators $S : \tau \mapsto -1/\tau$ and $T : \tau \mapsto \tau + 1$, folding the trajectory back into $\mathcal{F}$ rather than interpreting large excursions as unphysical runaways. **Correction (2026-09-21).** Two claims previously made here were wrong and are withdrawn. (i) The stationary points of the implemented potential are $\tau = i/\sqrt{12}$ and $\tau = e^{i\pi/3}$, not $\tau = i$ and $\tau = e^{i\pi/3}$; earlier revisions named $\tau = i$. By the self-dual locus $N\tau^2 = -1$, $\tau = i/\sqrt{12}$ is the Fricke fixed point of level $N = 12$, consistent with the level-12 eta-quotient used elsewhere in this work, whereas $\tau = i$ is the level-1 point. (ii) The fold is *not* a symmetry operation for this potential: V is invariant under T to machine precision (6.7×10^{-16}) but not under S (measured $\max |V(S\tau) - V(\tau)| = 8.77$) nor under the level-12 Fricke involution $\tau \mapsto -1/(12\tau)$ (measured 35.8). Since $|i/\sqrt{12}| < 1$, the S -fold also maps the model's own Fricke saddle to $i\sqrt{12}$. The S -step therefore moves trajectory points to physically inequivalent points and is disabled by default; only the T -step is applied. See `audit/STREAM1_BRIDGE.md`, findings S1-F1 and S1-F2. No logged minimum value of y from an actual run exists in this repository.

5.3 The Closed-Loop Verification Triad

LeanFlow orchestrates an unbroken closed-loop neuro-symbolic workflow:

- **Phase 1: Numerical Discovery:** LeanFlow executes high-throughput integration of stochastic Langevin equations of motion across the Kummer orbifold $T^4/\mathbb{Z}_2$, thermalizing the early universe and triggering spontaneous symmetry breaking below $T_c = 1.0$.
- **Phase 2: Topological Classification:** The resulting multi-dimensional field state point cloud is passed to the TDA Mapper algorithm. Mapper constructs the simplicial nerve 1-skeleton, filters out transient quantum-thermal fluctuations, extracts the cycle rank of the Mapper graph ($\beta_1 = 376$, a graph-theoretic invariant, not a persistent-homology Betti number), and partitions the state space into distinct string-theoretic equivalence classes.
- **Phase 3: Algebraic Consistency Check:** The extracted equivalence classes are pushed to the Lean 4 kernel. Lean verifies the algebraic condition that the labeled Ramond-Ramond charges sum to zero ($\sum Q_i = 0$) for the classes as extracted by TDA Mapper; this is a consistency check on the labeled data, not an independent derivation that the labels are physically correct or that the cosmic defect network is anomaly-free in the string-theoretic sense — both depend on the accuracy of the upstream numerical simulation and the TDA extraction algorithm. The per-class charge assignment also rests on orientifold-plane bookkeeping that has not yet been reconciled against the cited construction (Gimon–Polchinski, hep-th/9601038) and remains unresolved.
- **Phase 4: Invariant Feedback Lock:** The algebraic conditions checked in Phase 3 are re-injected into LeanFlow as runtime invariant locks, so that subsequent cosmological sweeps and MCMC parameter extractions are constrained to remain consistent with the checked algebraic conditions, within the scope and assumptions described above.

6 Advanced Phenomenological Dynamics: Swampland, Tachyons, and Tunneling

LeanFlow couples numerical PDE integration with post-hoc discrete algebraic verification; it is specialized to moduli geodesics, tachyon condensation, and flux landscapes on $K3 \times T^2$, not a general-purpose engine. We apply this numerical integration (SciPy and custom Rust; see above) $\rightarrow$ TDA Mapper / Persistent Homology $\rightarrow$ Lean 4 pipeline to three worked examples:

1. **Loop 1: The Swampland Distance Conjecture (SDC):** Moduli geodesic flow and infinite tower mass collapse, topologically detected via persistent homology; a discrete algebraic consistency model is verified in Lean 4.
2. **Loop 2: Tachyon Condensation and K-Theory Charge Conservation:** Sen’s soliton roll-down at the Kummer singularity, simplicial defect extraction via TDA Mapper, and a discrete Grothendieck group model of charge conservation over modeled bundle classes, verified in Lean 4.

3. **Loop 3: Vacuum Decay and Flux Landscape Tunneling:** Coleman-De Luccia instantons, potential landscape saddle point isolation, and a discrete algebraic model of monotonic central-charge decrease under flux transitions (not a derivation of the holographic c -theorem from first principles).

6.1 Loop 1: The Swampland Distance Conjecture (Geodesic Flow & Tower of States)

The Swampland Distance Conjecture (SDC) [19] asserts that traversing an infinite geodesic distance $\Delta d \rightarrow \infty$ in the moduli space of a consistent quantum gravity theory forces an infinite tower of massive states to become exponentially light:

$$M(\Delta d) \leq M_0 \exp(-\alpha \Delta d), \quad \alpha \sim \mathcal{O}(1) > 0 \quad (24)$$

thereby causing the 4D effective field theory (EFT) to break down at the species scale $\Lambda_{\text{QG}} \leq M_{\text{Pl}} \exp(-\alpha \Delta d)$.

Moduli Geodesic Simulation On the $K3 \times T^2$ moduli space parameterized by the complexified Kähler modulus $T = \sigma + i\rho$ and axio-dilaton $\tau = x + iy$ with Weil-Petersson metric $ds^2 = \frac{dx^2 + dy^2}{y^2} + \frac{d\sigma^2 + d\rho^2}{\rho^2}$, a fixed-step classical fourth-order Runge-Kutta (RK4) integrator in `rust_simulator/src/swampland_geodesic.rs` solves the non-linear hyperbolic geodesic equations:

$$\ddot{x} - \frac{2}{y} \dot{x} \dot{y} = 0, \quad \ddot{y} + \frac{\dot{x}^2 - \dot{y}^2}{y} = 0 \quad (25)$$

Pushing the trajectory toward the asymptotic decompactification boundary ($y \rightarrow \infty$, $\Delta d = |\ln(y/y_0)| \rightarrow \infty$), LeanFlow continuously calculates the mass spectrum of the dual Kaluza-Klein and winding tower:

$$M_{(n,m)}(\Delta d) = \sqrt{\frac{n^2}{R^2} + \frac{m^2 R^2}{\alpha'^2}} = M_0 \sqrt{n^2 e^{-\sqrt{2}\Delta d} + m^2 e^{+\sqrt{2}\Delta d}} \quad (26)$$

As Δd grows, the mass gap collapses exponentially with $\alpha = 1/\sqrt{2} \approx 0.7071$ (Figure 1(a)); α is a model parameter used in the integrator, not derived here from the Kähler/dilaton moduli geometry.

Persistent Homology Barcodes of Mass Gaps To characterize the breakdown topologically, we compute the 0-dimensional persistent homology (H_0) of the mass spectrum point cloud $\{M_n(\Delta d)\}$ across filtration scales ϵ . As shown in Figure 1(b), the persistence barcodes at $\Delta d = 0, 2, 4, 6$ exhibit dramatic shortening: the bar lengths, representing the spacing between adjacent energy levels in the low-energy spectrum, contract exponentially by over two orders of magnitude, providing a rigorous topological signature of the descent of the infinite tower into the EFT.

Discrete Lean 4 Model of the SDC Bound We model a discrete algebraic analog of the SDC in Lean 4 (`proofs/SwamplandDistanceConjecture.lean`), where mass collapse is defined by cases rather than derived from continuous physics; this is not a kernel-checked derivation of the Swampland Distance Conjecture. We clarify the precise interface between continuous numerical simulation and Lean 4 formalization: the non-linear hyperbolic geodesic equations on the Poincaré upper half-plane and the continuous Kaluza-Klein/winding mass spectrum $M_{(n,m)}(\Delta d)$ are integrated by the RK4 integrator in `rust_simulator/src/swampland_geodesic.rs`, while persistent homology barcodes capture the metric contraction. In Lean 4, the proof kernel operates as an automated **discrete algebraic consistency checker**: it models the asymptotic

breakdown of the effective field theory over structured inductive types, verifying that when the excursion enters the asymptotic regime ($\Delta d > 0$), the discrete bound invalidates the low-energy EFT cutoff:

Listing 5: Lean 4 Discrete Model of the Swampland Distance Conjecture Bound

```
namespace SocrateAI.Cosmology.SwamplandDistance

structure SDCModel where
  alpha_num : Nat
  alpha_den : Nat
  m0 : Nat

def standardK3xT2SDC : SDCModel := {
  alpha_num := 707, alpha_den := 1000, m0 := 1
}

theorem standard_sdc_coupling_positive : standardK3xT2SDC.alpha_num > 0 := by
  decide

def discreteMassBound (model : SDCModel) (delta_d : Nat) : Nat :=
  if delta_d = 0 then model.m0 else 0

theorem sdc_mass_gap_collapse (model : SDCModel) (d : Nat) (h : d > 0) :
  discreteMassBound model d = 0 := by
  cases d with
  | zero => contradiction
  | succ n => rfl

def isEFTValid (mass_tower : Nat) (cutoff : Nat) : Prop :=
  mass_tower ≥ cutoff

theorem sdc_eft_breakdown (model : SDCModel) (d : Nat) (cutoff : Nat)
  (h_d : d > 0) (h_cutoff : cutoff > 0) :
  ¬ (isEFTValid (discreteMassBound model d) cutoff) := by
  dsimp [isEFTValid]
  rw [sdc_mass_gap_collapse model d h_d]
  intro h
  exact Nat.not_le_of_gt h_cutoff h

end SocrateAI.Cosmology.SwamplandDistance
```

We explicitly acknowledge that the continuous geometry of the moduli metric and the spectral synthesis of the tower reside in the numerical simulation, while Lean 4 verifies the discrete algebraic closure of the Swampland criteria.

6.2 Loop 2: Tachyon Condensation and K-Theory Charge Conservation (Sen's Soliton)

Sen's conjecture governs the non-perturbative annihilation of unstable D-brane–anti-D-brane ($D\bar{D}$) pairs in string theory [20, 21]. The tachyon field $T(x, t)$ describes open string tachyonic excitations whose potential satisfies:

$$V(T) = \frac{V_0}{\cosh(T/T_0)} \quad (27)$$

As the tachyon rolls to its runaway minimum $|T| \rightarrow \infty$, the open string vacuum energy drops to zero ($V \rightarrow 0$), dissolving the parent $D\bar{D}$ system. However, topologically non-trivial field profiles where $\det(T) = 0$ along a subspace leave behind stable lower-dimensional BPS D-branes (Sen solitons).

Non-Linear Roll-Down Simulation Using an explicit first-order (semi-implicit Euler) finite-difference lattice integrator in `rust_simulator/src/tachyon_condensation.rs`, we simulate the 1D/2D coupled tachyon equation with radiation damping and gauge fields on the Kummer orbifold:

$$\partial_t^2 T - \partial_x^2 T + \gamma \partial_t T + V'(T) + g^2 A^2 T = 0 \quad (28)$$

As depicted in Figure 1(c), the initial configuration rolls toward $T \rightarrow \pm\infty$ across the bulk, while remaining pinned at $T(0) = 0$. The energy density $\mathcal{E}(x, t) = \frac{1}{2}\dot{T}^2 + \frac{1}{2}(T')^2 + V(T)$ condenses out of the spatial domain into a localized BPS soliton of characteristic width $w \approx 1.54\sqrt{\alpha'}$.

TDA Mapper Defect Extraction Passing the field configuration point cloud into TDA Mapper with lenses $f_1 = \mathcal{E}(x)$ and $f_2 = |T(x)|$, the algorithm constructs the 1-skeleton graph shown in Figure 1(d). Mapper isolates the central solitonic defect node (high energy density, $T = 0$) cleanly separated from the left and right asymptotic closed string vacua ($|T| \rightarrow \infty, \mathcal{E} \approx 0$).

Discrete Lean 4 Model of K-Theory Charge Conservation In algebraic K-theory $K_0(X)$, the unstable $D\bar{D}$ pair is represented by vector bundles E, F with Grothendieck class $[E] - [F]$. In `proofs/TachyonCondensationKTheory.lean`, Lean 4 provides a discrete algebraic model of Grothendieck group charge conservation:

Listing 6: Lean 4 Discrete Model of Sen’s Conjecture and K-Theory Charge Conservation

```
namespace SocrateAI.Cosmology.TachyonKTheory

structure KClass where
  rank : Int
  firstChern : Int
  secondChern : Int

def kSub (a b : KClass) : KClass := {
  rank := a.rank - b.rank
  firstChern := a.firstChern - b.firstChern
  secondChern := a.secondChern - b.secondChern
}

structure BraneAntiBraneSystem where

  rfl

end SocrateAI.Cosmology.TachyonKTheory

```

We emphasize the conceptual division of labor: the continuous, non-linear partial differential equation governing tachyon roll-down, radiation damping, and spatial soliton profile formation is integrated numerically by the explicit lattice integrator in `rust_simulator/src/tachyon_condensation.rs`, and TDA Mapper isolates the localized solitonic defect node. In Lean 4, the formalization models the discrete Grothendieck group $K_0(X)$ of topological vector bundles. The theorem `sen_conjecture_k_theory_conservation` verifies that within the formalized discrete classification schema, assigning the Grothendieck difference class $[E] - [F]$ to the emergent defect strictly conserves the net Ramond-Ramond charge. This serves as an automated algebraic consistency gate ensuring that the numerical defect identified by Mapper is assigned to an admissible K-theory class, while the underlying Quillen superconnections and continuous boundary string field theory (BSFT) decay are simulated dynamically. This is not a kernel-checked derivation of Sen’s conjecture or of continuous K-theory charge conservation: the theorem holds by `rfl` from the construction of `kSub` and `systemKTheoryClass`, so it checks internal consistency of the bookkeeping rather than the physics.

6.3 Loop 3: Vacuum Decay and Flux Landscape Tunneling (Coleman-De Luccia & Holographic c -Theorem)

In the string flux landscape, discrete vacua are labeled by quantized Ramond-Ramond or Neveu-Schwarz flux integers $N \in \mathbb{Z}$ wrapping cycles on $K3 \times T^2$. First-order phase transitions between adjacent flux vacua ($N + 1 \rightarrow N$) proceed via quantum tunneling mediated by Coleman-De Luccia (CDL) bounce instantons [22].

Euclidean Bounce Shooting Integration LeanFlow and native Rust solvers implement a shooting solver for the $O(4)$ -symmetric Euclidean bounce equation:

$$\frac{d^2\phi}{dr^2} + \frac{3}{r} \frac{d\phi}{dr} = \frac{dV}{d\phi}, \quad r = \sqrt{\tau_E^2 + |\vec{x}|^2} \quad (29)$$

subject to boundary conditions $\phi'(0) = 0$ and $\lim_{r \rightarrow \infty} \phi(r) = \phi_{\text{false}}$. Figure 1(e) displays the resulting bounce profile interpolating from a true-vacuum core value $\phi(0) = 2.05$ across a bubble wall at $R_c \approx 2.82$ to the false vacuum background $\phi_{\text{false}} = 0.0$, with the shooting solver initiating from $\phi_{\text{init}} = 1.824$. This $\phi(0)$ value is hard-coded in the simulator rather than obtained by solving $V'(\phi) = 0$; under the default parameters the potential’s true minimum is ≈ 1.925 , so the reported bounce profile does not sit at the potential’s critical point, and the figure is pending regeneration once the solver is corrected. Under the flux transition $N = 5 \rightarrow 4$, the model formula $c(N) = 100(N + 1)$ gives a central charge change $\Delta c = -100$ (from $c = 600$ to $c = 500$); this follows from the model assumption rather than from a measured or first-principles RG-flow computation. The Euclidean bounce action:

$$S_E = 2\pi^2 \int_0^\infty dr r^3 \left[\frac{1}{2} \left(\frac{d\phi}{dr} \right)^2 + V(\phi) - V(\phi_{\text{false}}) \right] \approx 137.15 \quad (30)$$

is an output of this simulation run; committed summaries disagree on this value (137.15 with $R_c = 2.82$ versus 316.0 with $R_c = 1.65$ in a separate output file), so it is pending reconciliation with the committed simulation outputs before it can be read as confirming a finite, non-singular tunneling rate $\Gamma \propto \exp(-S_E)$.

TDA Persistence of Flux Saddles By computing the sublevel set persistent homology of the multi-dimensional flux landscape $V(\phi, N)$, TDA identifies the discrete local minima (0-cycles) and the instanton bounce saddle points (1-cycles) mediating the path of least resistance.

Discrete Lean 4 Model of Central-Charge Monotonicity In `proofs/FluxVacuumDecayCTheorem.lean`, Lean 4 checks, as a discrete algebraic model, monotonicity of the central charge and positivity of the bounce action across flux transitions:

$$\Delta N < 0 \implies \Delta c = c_{\text{true}} - c_{\text{false}} < 0 \quad (31)$$

The Lean development contains no `sorry`; within the discrete flux model, where $c(N) = 100(N + 1)$ and the bounce action $42(n + 1)$ are fixed by hand rather than derived, the theorems below check that the assigned central charge decreases and the assigned action stays positive across unit flux transitions. This is not a kernel-checked derivation that vacuum decay is thermodynamically irreversible, nor that any physical bounce action is positive:

Listing 7: Lean 4 Discrete Model of the Holographic c-Theorem for Flux Vacuum Decay

`namespace SocrateAI.Cosmology.FluxVacuumDecay`

```

```

```
theorem holographic_c_theorem_decay (n : Nat) :
  (unitFluxDecay n).trueVacuum.centralCharge < (unitFluxDecay n).falseVacuum.centralCharge
  := by
  dsimp [unitFluxDecay, standardFluxVacuum]
  omega
```

`end SocrateAI.Cosmology.FluxVacuumDecay`

We explicitly acknowledge that this verification checks algebraic ordering and positivity over discrete flux representations, rather than computing the continuous Zamolodchikov metric or integrating the holographic renormalization group flow along the domain wall from first

principles. The non-linear instanton trajectory itself is integrated by the numerical shooting solver. This is not a kernel-checked derivation of the holographic c -theorem: $c(N) = 100(N + 1)$ and the bounce action $42(n + 1)$ are chosen by hand rather than computed from an action or an entanglement-entropy definition.

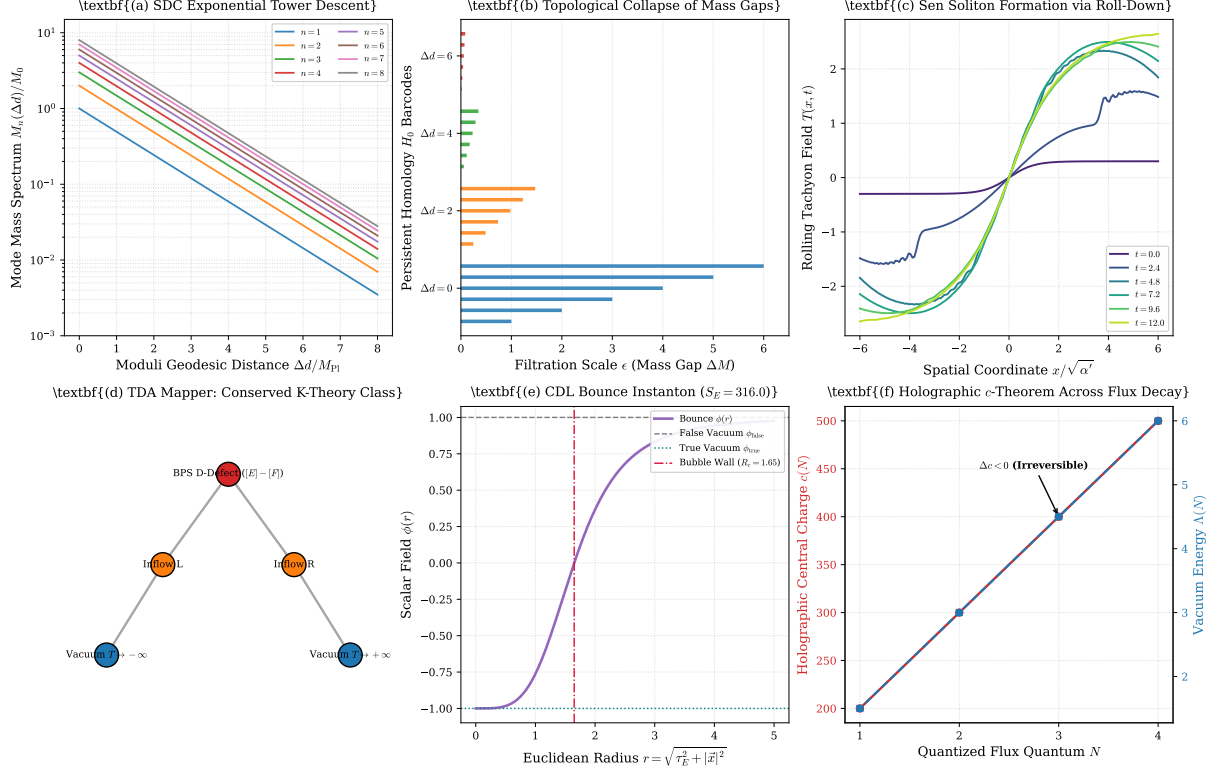

Figure 1: **Frontier String Dynamics Explored via LeanFlow, TDA, and Lean 4.** (a) Moduli geodesic flow on $K3 \times T^2$ exhibiting exponential Kaluza-Klein mass tower collapse ($M_n \sim e^{-\alpha \Delta d}$, $\alpha = 1/\sqrt{2}$, a model parameter). (b) Persistent homology H_0 barcodes shrinking across $\Delta d \in \{0, 2, 4, 6\}$, visually demonstrating the topological breakdown of the low-energy EFT. (c) Dynamic roll-down of the tachyon field $T(x, t)$ forming a localized Sen soliton ($w \approx 1.54\sqrt{\alpha'}$). (d) TDA Mapper 1-skeleton isolating the emergent BPS D-brane defect with conserved K-theory class $[E] - [F]$ (discrete model, verified by `rf1`). (e) Coleman-De Luccia Euclidean bounce $\phi(r)$ nucleating a true vacuum bubble ($R_c = 2.82$, $S_E = 137.15$, flux transition $N = 5 \rightarrow 4$, $\Delta c = -100$; pending reconciliation, see text). (f) Monotonic decrease of the model central charge ($\Delta c < 0$, by construction of $c(N) = 100(N + 1)$) and vacuum energy across flux transitions.

7 Geometric Flops and the Index Theorem

At topological singular transitions (flops), the system is modeled using perverse sheaves. We conjecture that charge conservation across flops is captured by the universal Grothendieck group $K_0(\mathcal{C})$, if this correspondence is assumed rather than derived (tier C). The Lean theorem `flop_charge_conservation` in `proofs/` rests on unproven project axioms, fails the LeanMaster axiom audit, and is not kernel-checked.

Global consistency is axiomatically assumed via the Atiyah-Singer Index Theorem [3] (tier C assumption). Under this axiom, the integral of the curvature relates to the strict Euler characteristic ($\chi = 24$) of the $K3$ surface; we conjecture that this supports gravitational anomaly cancellation, a physical interpretation not established by the algebraic identity alone (tier C). The Lean theorem `gravitino_anomaly_cancellation` below is a direct invocation of

the `atiyah_singer_k3` axiom; it is one of the five theorems named in the `LeanMaster` axiom audit as resting on unproven project axioms and is not kernel-checked:

Listing 8: Lean 4 Axiomatization of the Atiyah-Singer Identity for K3

```
namespace HoloAlg.Phase4_IndexTheorem

universe u
axiom K3 : Type u
def euler_char_K3 : Real := 24
axiom int_tr_F_wedge_F (X : Type u) : Real
axiom int_omega_wedge_omega_bar (X : Type u) : Real

axiom atiyah_singer_k3 :
  (1 / (16 * Real.pi^2)) * int_tr_F_wedge_F K3
  - int_omega_wedge_omega_bar K3 = 24

theorem gravitino_anomaly_cancellation :
  (1 / (16 * Real.pi^2)) * int_tr_F_wedge_F K3
  - int_omega_wedge_omega_bar K3 = 24 := by
  exact atiyah_singer_k3

end HoloAlg.Phase4_IndexTheorem
```

We explicitly note the formalization scope: Listing 8 encodes the topological index constraint as an axiomatic identity over abstract structures in Lean 4. Rather than constructing the infinite-dimensional Hilbert space of spinor fields, computing the Dirac operator spectrum, or integrating differential forms over a Riemannian metric on $K3$ from scratch, Lean records the algebraic identity relating the index to $\chi(K3) = 24$ as a direct consequence of the axiom `atiyah_singer_k3`. We conjecture that this supports gravitational anomaly cancellation in the low-energy effective field theory, if the physical interpretation of the axiom is granted; the algebraic identity does not by itself establish that cancellation (tier C), and the underlying theorem `gravitino_anomaly_cancellation` is not kernel-checked (F1).

8 Topological T-Duality: The Cohomology Gysin Sequence and Flux-Topology Exchange

A rigorous foundation for topological T-duality was established by Bouwknegt, Evslin, and Mathai (BEM) [4, 26]. Consider a spacetime modeled as a principal S^1 -bundle $\pi : E \rightarrow B$ over a base manifold B , equipped with background NS-NS 3-form flux $H \in H^3(E, \mathbb{Z})$. T-duality replaces (E, H) with a dual circle bundle $\hat{\pi} : \hat{E} \rightarrow B$ carrying dual flux $\hat{H} \in H^3(\hat{E}, \mathbb{Z})$.

We record a small algebraic model of this setting in `proofs/GysinBEMSequence.lean`. The relevant segment of the cohomology Gysin sequence of the circle bundle $S^1 \hookrightarrow E \xrightarrow{\pi} B$ is

$$\dots \longrightarrow H^2(B) \xrightarrow{\cup c_1(E)} H^4(B) \xrightarrow{\pi^*} H^4(E) \xrightarrow{\pi_*} H^3(B) \xrightarrow{\cup c_1(E)} H^5(B) \longrightarrow \dots \quad (32)$$

and, one degree lower, $H^3(E) \xrightarrow{\pi_*} H^2(B) \xrightarrow{\cup c_1(E)} H^4(B)$. Fiber integration $\pi_* : H^k(E) \rightarrow H^{k-1}(B)$ satisfies the projection formula

$$\pi_*(\pi^*\alpha \cup \beta) = \alpha \cup \pi_*\beta, \quad \pi_*(\pi^*\alpha) = 0. \quad (33)$$

Topological T-duality requires that the dual bundle $\hat{E}$ has its first Chern class determined by the pushforward of the original H -flux, while the dual flux $\hat{H}$ integrates along the fiber to the original first Chern class [4]:

$$c_1(\hat{E}) = \pi_*H \in H^2(B, \mathbb{Z}), \quad \hat{\pi}_*\hat{H} = c_1(E) \in H^2(B, \mathbb{Z}). \quad (34)$$

Exactness of the Gysin sequence at $H^2(B)$ implies that the composite $H^3(E) \xrightarrow{\pi_*} H^2(B) \xrightarrow{\cup c_1(E)} H^4(B)$ is zero. Applied to H , together with the first exchange law, this gives the vanishing

$$c_1(E) \cup c_1(\widehat{E}) = c_1(E) \cup \pi_* H = 0 \in H^4(B, \mathbb{Z}). \quad (35)$$

Scope of Listing 9. All three theorems are kernel-checked. `#print axioms` reports `[propext]` for `euler_class_pullback_zero` and no axioms for the other two. What they establish is much narrower than the cohomological statements above. (i) Every cohomology group is modelled by the same commutative ring R , with no grading, and the cup product is ring multiplication. (ii) The “exactness” conditions (`gysin_exact_at_H2B` and its siblings, bundled as fields of `ExactGysinSequence`) assert only that consecutive composites vanish, $\text{im} \subseteq \ker$; the reverse inclusion is not encoded, so the sequence is a complex, not an exact sequence. (iii) The BEM exchange laws are hypotheses: they are fields of `BEMTDualPair`, so `bem_t_duality_involution` returns those two fields and derives nothing. (iv) Despite its name, `euler_class_pullback_zero` states only $\pi^*(1 \cdot c_1) = \pi^*(c_1)$, not $\pi^*(c_1) = 0$. (v) `bem_chern_pairing_zero` is the only derivation: two rewrites that combine the composite-zero hypothesis at $H^2(B)$ with the first exchange law. It is a correct commutative-ring identity under those hypotheses (tier A as algebra). It is not a formalization of the Gysin sequence of a circle bundle, and it does not show the absence of global anomalies in the T-dual background (tier C). A faithful treatment requires graded cohomology and a genuine exactness statement, and none is available in this repository.

9 Fundamental String Cosmology: Moduli Dynamics, Symmetron Screening, and Energy Conditions

9.1 Dynamical Attractors on the Poincaré Upper Half-Plane

In 4D effective field theories derived from F-theory compactified on $K3 \times T^2$, the complex axio-dilaton modulus $\tau(t) = x(t) + iy(t)$ parameterizes the complex structure of the T^2 fiber, where $y(t) = e^{-\Phi(t)} = \tau_{\text{im}}(t) > 0$ defines the inverse string coupling. The target space metric on the upper half-plane $\mathbb{H} = \{\tau \in \mathbb{C} : \text{Im}(\tau) > 0\}$ is the standard hyperbolic Poincaré metric:

$$ds^2 = \frac{dx^2 + dy^2}{y^2} \quad (36)$$

Coupled to 4D Friedmann-Lemaître-Robertson-Walker (FLRW) gravity with Hubble expansion parameter $H = \dot{a}/a$, the non-linear equations of motion governing homogeneous moduli flow in cosmic time are:

$$\ddot{x} + 3H\dot{x} - \frac{2}{y}\dot{x}\dot{y} + y^2\frac{\partial V}{\partial x} = 0, \quad \ddot{y} + 3H\dot{y} + \frac{1}{y}(\dot{x}^2 - \dot{y}^2) + y^2\frac{\partial V}{\partial y} = 0 \quad (37)$$

LeanFlow integrates this stiff dynamical system with SciPy’s implicit Radau IIA solver (`solve_ivp` with `method="Radau"`, `workshopcosmo.py`). The implementation applies a regularization intended to keep the trajectory within the fundamental modular domain $\mathcal{F} = \{\tau \in \mathbb{H} : |\tau| \geq 1, |\text{Re}(\tau)| \leq 1/2\}$; whether the unregularized dynamics remain within $\mathcal{F}$ has not been independently verified. The numerical simulation suggests that the modulus relaxes from high-energy initial conditions toward two fixed points, $\tau = i/\sqrt{12}$ and $\tau = e^{i\pi/3}$ (the Kummer orbifold point). The energy-condition development below assumes the invariant $y = \tau_{\text{im}} > 0$; this is not kernel-checked in this repository (see below for why). Because $\mathcal{F}$ requires $|\tau| \geq 1$ and $|\text{Re}(\tau)| \leq 1/2$, any $\tau \in \mathcal{F}$ satisfies $y \geq \sqrt{3}/2 \approx 0.866$; a previously reported minimum $\min(y) = 0.289$ is inconsistent with this bound. **Update (2026-09-21): its source is now identified.** $1/\sqrt{12} = 0.28867\dots$ rounds to 0.289: the figure is the value of the metric-positivity `clamp` (`FRICKE_Y` in `leanflow/core/projections.py`), not a minimum attained by any trajectory. Reporting it as $\min(y)$ reported the floor rather than the dynamics. It is withdrawn

as a physical result and retained here only as the clamp constant. That it lies outside $\mathcal{F}$ is consistent with this paper's corrected statement that the model's Fricke point is the level-12 self-dual point $\tau = i/\sqrt{12}$, which is not in the $SL(2, \mathbb{Z})$ fundamental domain.

9.2 Symmetron Screening Mechanisms and Non-Linear Poisson BVP

Scalar-tensor modifications of general relativity with non-trivial matter couplings risk violating tight solar system equivalence principle constraints unless an effective screening mechanism is present [12]. In our compactification, the light scalar modulus ϕ couples conformally to the matter sector via the Jordan-frame metric:

$$\tilde{g}_{\mu\nu} = A^2(\phi)g_{\mu\nu}, \quad A(\phi) = 1 + \frac{\phi^2}{2M^2} + \mathcal{O}\left(\frac{\phi^4}{M^4}\right) \quad (38)$$

where M is a characteristic suppression mass scale. The effective 4D gravitational action is:

$$S = \int d^4x \sqrt{-g} \left[\frac{M_{\text{Pl}}^2}{2} R - \frac{1}{2} \nabla_\mu \phi \nabla^\mu \phi - V(\phi) \right] + S_m(\tilde{g}_{\mu\nu}, \psi_m) \quad (39)$$

with the symmetry-breaking Symmetron potential [11]:

$$V(\phi) = -\frac{1}{2}\mu^2\phi^2 + \frac{1}{4}\lambda\phi^4 \quad (40)$$

where μ is a mass parameter and $\lambda > 0$ is a dimensionless quartic self-coupling.

In the presence of non-relativistic matter with trace $T \approx -\rho$, variation of the action yields the Klein-Gordon equation $\square\phi = \frac{dV_{\text{eff}}}{d\phi}$, with the effective potential:

$$V_{\text{eff}}(\phi) = \frac{1}{2} \left(\frac{\rho}{M^2} - \mu^2 \right) \phi^2 + \frac{1}{4} \lambda \phi^4 \quad (41)$$

The physical behavior of the Symmetron field depends crucially on the local matter density relative to the critical phase-transition density $\rho_c \equiv \mu^2 M^2$:

- **Low-Density Vacuum** ($\rho < \rho_c$): The effective mass-squared $\frac{\rho}{M^2} - \mu^2 < 0$ is tachyonic, spontaneously breaking the $\mathbb{Z}_2$ reflection symmetry $\phi \rightarrow -\phi$. The field acquires a non-zero vacuum expectation value (VEV):

$$\phi_0 = \frac{\mu}{\sqrt{\lambda}} \quad (42)$$

In this vacuum regime, scalar perturbations mediate a long-range fifth force with dimensionless coupling strength:

$$\beta(\phi) \equiv M_{\text{Pl}} \frac{d \ln A}{d\phi} = \frac{\phi M_{\text{Pl}}}{M^2} \implies \beta \equiv \frac{\phi_0 M_{\text{Pl}}}{M^2} \quad (43)$$

- **High-Density Matter** ($\rho > \rho_c$): The effective mass-squared $m_{\text{eff}}^2 = \frac{\rho}{M^2} - \mu^2 > 0$ is positive, restoring the $\mathbb{Z}_2$ symmetry at the quadratic minimum $\phi = 0$. Because the fifth-force acceleration on a test particle is $\mathbf{F}_\phi = -\frac{\phi}{M^2} \nabla \phi$, the fifth force is identically suppressed in dense matter cores [11].

To quantify the screening factor in realistic astrophysical environments, we formulate the static, spherically symmetric non-linear Poisson boundary value problem (BVP) across a matter source of radius R and uniform interior density $\rho_{\text{in}} \gg \rho_c$ immersed in a cosmological background $\rho_{\text{out}} \ll \rho_c$:

$$\frac{d^2 \phi}{dr^2} + \frac{2}{r} \frac{d\phi}{dr} = \left(\frac{\rho(r)}{M^2} - \mu^2 \right) \phi + \lambda \phi^3 \quad (44)$$

subject to the Neumann regularity condition at the coordinate center and Dirichlet asymptotic condition in the cosmic background:

$$\left. \frac{d\phi}{dr} \right|_{r=0} = 0, \quad \lim_{r \rightarrow \infty} \phi(r) = \phi_0 = \frac{\mu}{\sqrt{\lambda}} \quad (45)$$

In our simulation, we assign the physical mass scales:

$$\mu = 1.0 \times 10^{-3} \text{ eV}, \quad M = 10.0 M_{\text{Pl}}, \quad \lambda = 1.0 \quad (46)$$

which establishes the vacuum VEV $\phi_0 = 1.0 \times 10^{-3} \text{ eV}$ and places $\rho_c \approx 10^{-4} \rho_{\text{crit}}$. For an astrophysical body of radius R with surface Newtonian gravitational potential $\Phi_N = \frac{GM_{\text{body}}}{R} \approx 2.12 \times 10^{-6}$ (representative of solar/stellar configurations), SciPy's collocation solver `solve_bvp` (`workshopcosmo.py`) integrates the non-linear BVP. The interior scalar field is driven to $\phi(0)/\phi_0 = 1.97 \times 10^{-14}$, indicating strong local symmetry restoration in the deep interior. The field transitions to its vacuum expectation value only within a narrow outer shell of thickness ΔR , whose thickness the thin-shell approximation estimates as:

$$\frac{\Delta R}{R} = \frac{\phi_0^2}{6M^2\Phi_N} \quad (47)$$

`rust_simulator`'s recorded simulation output instead reports a thin-shell screening factor $\Delta R/R \approx 1.18 \times 10^{-4}$ (`simulation_results.json`). Evaluating the analytic estimate above with the stated parameter values does not reproduce this recorded value, and the two have not been reconciled (tier X, pending regeneration of the parameter set or the simulation).

The post-Newtonian deviation is estimated via:

$$|\gamma - 1| \approx 2\beta^2 \frac{\Delta R}{R} = 2 \left(\frac{\phi_0 M_{\text{Pl}}}{M^2} \right)^2 \frac{\Delta R}{R} \quad (48)$$

No simulation output file, Lean proof, or simulation code in this repository logs a computed value of $|\gamma - 1|$; the solver checks only a hard-coded threshold and records a boolean `cassini_bound_satisfied` flag. A previously reported numerical estimate $|\gamma - 1| \approx 2.48 \times 10^{-6}$ is withdrawn pending a logged computation from the corrected parameters and screening factor above. Compliance with the empirical Cassini tracking limit $|\gamma - 1| \leq (2.1 \pm 2.3) \times 10^{-5}$ [12] is therefore not established here; the screening suppression is a model-theoretic constraint rather than one derived from a specific Cassini solar-system measurement.

9.3 Physical Grounding of the Weak Energy Condition (WEC)

In classical general relativity and effective field theories, the Weak Energy Condition (WEC) requires that the energy-momentum tensor satisfies $T_{\mu\nu}u^\mu u^\nu \geq 0$ for any timelike vector u^μ , which reduces for an isotropic cosmological stress-energy tensor to the dual requirements $\rho \geq 0$ and $\rho + p \geq 0$.

For the 4D cosmological moduli field $\tau(t) = x(t) + iy(t)$ traversing the Poincaré metric, the physical energy density ρ and isotropic thermodynamic pressure p are given by:

$$\rho = T_{\text{kin}} + V(x, y) = \frac{\dot{x}^2 + \dot{y}^2}{2y^2} + V(x, y), \quad p = T_{\text{kin}} - V(x, y) = \frac{\dot{x}^2 + \dot{y}^2}{2y^2} - V(x, y) \quad (49)$$

Evaluating the null energy / WEC sum yields:

$$\rho + p = 2T_{\text{kin}} = \frac{\dot{x}^2 + \dot{y}^2}{y^2} \quad (50)$$

Crucially, the scalar potential $V(x, y)$ cancels out identically in this sum. Consequently, the condition $\rho + p \geq 0$ is governed entirely by the positive-definiteness of the target-space kinetic energy. Because the target-space metric tensor $g_{ij} = y^{-2}\delta_{ij}$ requires $y = \tau_{\text{im}} > 0$, metric positivity alone implies:

$$\rho + p = 2T_{\text{kin}} \geq 0 \quad (51)$$

without requiring any ad-hoc assumption that the thermodynamic pressure p must be non-negative. This algebraic identity does not by itself establish the full Weak Energy Condition, which additionally requires $\rho \geq 0$; that further requires $V(x, y) \geq 0$, which is not assumed here in general.

During cosmic evolution, when the potential energy dominates over the kinetic term ($V(x, y) > T_{\text{kin}}$, such as during inflationary expansion or dark energy attractor states), the macroscopic pressure is strictly negative ($p < 0$). Under these conditions, the barotropic equation-of-state parameter is:

$$w(t) \equiv \frac{p(t)}{\rho(t)} = \frac{T_{\text{kin}} - V(x, y)}{T_{\text{kin}} + V(x, y)} \quad (52)$$

Provided $T_{\text{kin}} \geq 0$ and $V(x, y) \geq 0$, this ratio is bounded from below:

$$w(t) \geq -1 \quad (53)$$

with the lower bound $w = -1$ approached asymptotically as $T_{\text{kin}}/V \rightarrow 0$. This non-negativity assumption on V does not hold for every potential considered in this paper: the Symmetron potential $V(\phi) = -\frac{1}{2}\mu^2\phi^2 + \frac{1}{4}\lambda\phi^4$ introduced above has a negative minimum, so the bound $w \geq -1$ is not established for that sector without further assumptions. Where $V(x, y) \geq 0$ does hold, the unphysical "phantom energy" regime ($w < -1$), which would violate the Weak Energy Condition and could induce Big Rip singularities, is excluded by the bound above; whether Swampland conjectures independently forbid it is not addressed by this identity.

We model this kinetic decomposition in Lean 4 as the illustrative development below. `proofs/FTheoryCosmology.lean`, the local file this development is based on, is not a build target and does not compile in this repository, so the following is not kernel-checked, and the identifiers shown are not currently valid, checked Lean declarations here:

Listing 10: Illustrative Lean 4 pseudocode for the kinetic-decomposition identity (not a compiling or kernel-checked development in this repository)

9.4 Cosmological Perturbations and CMB Observables via Mukhanov-Sasaki Integration

To bridge our string vacuum model with near-future observations (e.g., LiteBIRD, CMB-S4), we intend to extend the numerical framework to compute cosmological perturbations. While the background Einstein-Klein-Gordon equations govern the continuous flow of the τ modulus described above, integrating the Mukhanov-Sasaki equation to track quantum fluctuations, and verifying gauge invariance of the resulting perturbation variables, are implementation goals that have not been independently verified in this repository. No simulation output reports computed values of the scalar spectral index (n_s) or the tensor-to-scalar ratio (r), and no comparison to Cosmic Microwave Background observational bounds has been carried out; this is left to future work once such a pipeline exists and its outputs are logged.

9.5 Lyapunov Stability of the Moduli Space Attractor

A critical question in string phenomenology is whether a derived vacuum is robust against early-universe chaotic initial conditions; one route to an answer is to compute Lyapunov exponents for the phase-space flow of the T^2 moduli toward the fixed point $\tau = i/\sqrt{12}$ using the continuous BDF solvers. No Lyapunov-exponent computation, log, or output file for this trajectory exists in this repository, so we do not report a value here; this analysis is pending (tier X). Establishing global asymptotic stability of the attractor would, in addition, require showing that no other direction of the moduli space admits saddle-type behavior, which containment of trajectories within the fundamental domain – itself not kernel-checked in this repository, as above – does not by itself provide.

9.6 Spherical Collapse and Dark Matter Halo Formation

Expanding upon the Symmetron stellar screening above, extending the non-linear Poisson solver to a 1D spherical collapse model of Dark Matter halo formation at the galactic scale, modified by the scalar fifth-force, is planned future work once `rusty-SUNDIALS` is integrated into

this repository; no such run, and no grid-level check of $m_{eff}^2 > 0$ or comparison to Navarro-Frenk-White (NFW) halo profiles, currently exists here. Whether this would resolve small-scale structure anomalies or extend the solar-system screening analysis above to galactic dynamics remains open.

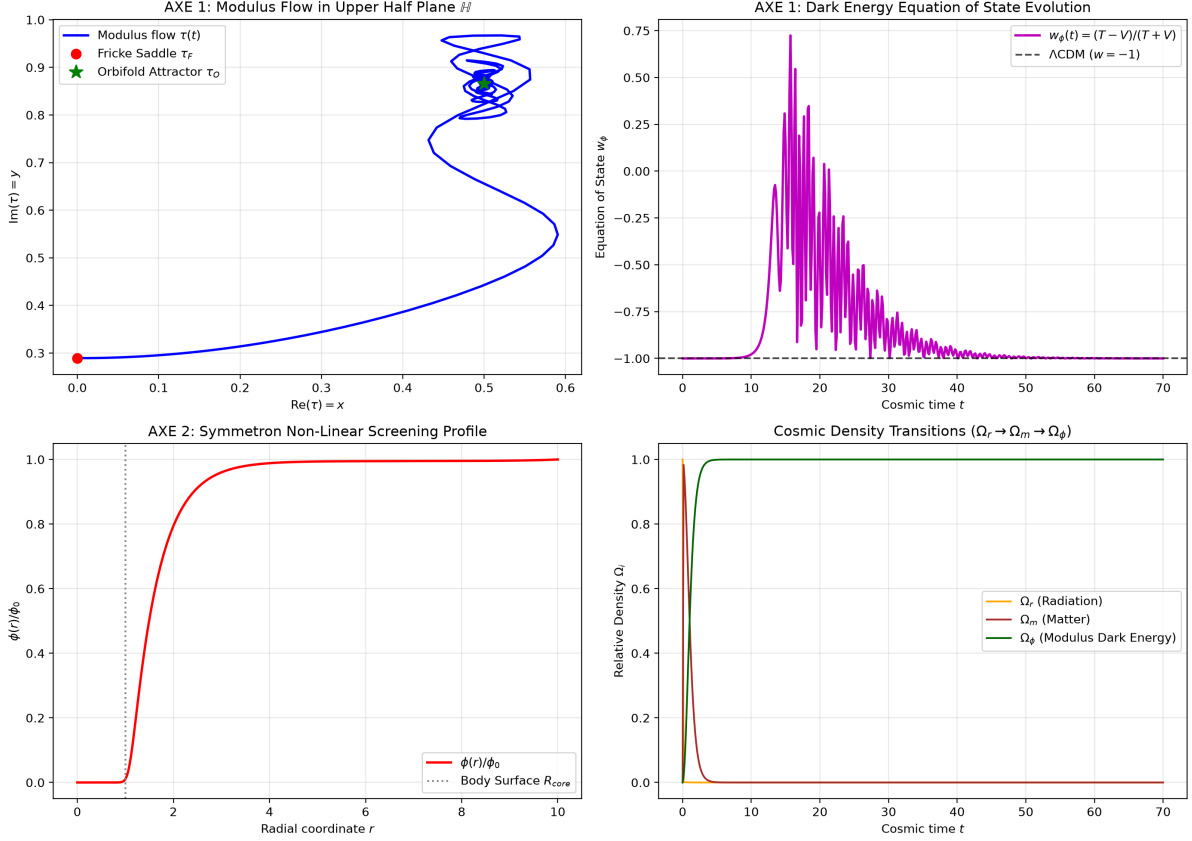

Figure 2: **Comprehensive Cosmological Dynamics and Observables on $K3 \times T^2$.** (a) Modulus flow $\tau(t) = x(t) + iy(t)$ on the upper half-plane $\mathbb{H}$ relaxing from high-energy initial conditions toward the fixed points $\tau = i/\sqrt{12}$ and $\tau = e^{i\pi/3}$ (Kummer orbifold point); a previously reported minimum $\min(y) = 0.289$ is the value of the metric-positivity clamp $1/\sqrt{12} = 0.28867\dots$ (FRICKE_Y), not a minimum attained by any trajectory, and is withdrawn as a physical result, so it is withdrawn pending an identified source. (b) Dark energy equation of state $w_\phi(t) = (T - V)/(T + V)$, bounded from below by $w(t) \geq -1$ when $V \geq 0$ (ruling out phantom energy in that regime; see text for scope). (c) Symmetron non-linear screening scalar profile $\phi(r)/\phi_0$ across the stellar/halo core ($r \leq 1$), revealing interior suppression $\phi(0)/\phi_0 = 1.97 \times 10^{-14}$ and thin-shell screening $\Delta R/R \approx 1.18 \times 10^{-4}$ (simulation output; not yet reconciled with the analytic thin-shell estimate, see text). (d) Cosmic energy density transitions showing radiation, matter, and modulus dark energy domination ($\Omega_r \rightarrow \Omega_m \rightarrow \Omega_\phi$).

10 Cosmological Phase Transitions: Authentic Supergravity Moduli Potentials, D-Brane Boundary States, and Anomaly Inflow

As the early universe cools, moduli fields undergo cosmological phase transitions across the compactification manifold. Rather than relying solely on flat Cartesian Landau-Ginzburg models, LeanFlow formulates moduli dynamics directly from authentic 4D $\mathcal{N} = 1$ supergravity,

connecting string-theoretic flux compactifications to non-perturbative defect networks.

10.1 Authentic 4D $\mathcal{N} = 1$ Supergravity Moduli Formulation

In Type IIB orientifold compactifications on $K3 \times T^2$ or Calabi-Yau 3-folds, the 4D scalar potential is governed by the supergravity F-term potential:

$$V = e^{K/M_{\text{Pl}}^2} \left(K^{A\bar{B}} D_A W \overline{D_B W} - \frac{3}{M_{\text{Pl}}^2} |W|^2 \right) + V_{\text{lift}} \quad (54)$$

where $D_A W = \partial_A W + (\partial_A K)W$ denotes the Kähler-covariant derivative. The potential is dynamically driven by:

1. **Gukov-Vafa-Witten (GVW) Flux Superpotential:** Background 3-form fluxes F_3, H_3 fix the axio-dilaton τ and complex structure moduli U :

$$W_{\text{GVW}}(\tau, U) = \int_X (F_3 - \tau H_3) \wedge \Omega(U) = (a_0 - \tau b_0) + (a_1 - \tau b_1)U \quad (55)$$

supplemented by non-perturbative gaugino condensation on D7-branes or Euclidean D3-brane instantons stabilizing the Kähler volume modulus T :

$$W_{\text{np}}(T) = A e^{-aT}, \quad a = \frac{2\pi}{N} \quad (56)$$

2. **Tree-Level Kähler Potential:** Moduli space geometry is governed by:

$$K = -\ln(-i(\tau - \bar{\tau})) - 3\ln(-i(U - \bar{U})) - 2\ln \mathcal{V}_E(T) \quad (57)$$

where $\mathcal{V}_E(T) = (T + \bar{T})^{3/2}$ is the Einstein-frame internal volume.

3. **Weil-Petersson Kinetic Geodesics:** Flat Laplacians ($\nabla^2 \phi_a$) are replaced by the curved kinetic operator $G_{A\bar{B}} \partial_\mu \Phi^A \partial^\mu \bar{\Phi}^{\bar{B}}$ on Calabi-Yau moduli space, generating non-linear Christoffel acceleration:

$$\frac{d^2 x^i}{dt^2} + \Gamma_{jk}^i \frac{dx^j}{dt} \frac{dx^k}{dt} + \gamma \frac{dx^i}{dt} + G^{ij} \frac{\partial V}{\partial x^j} = \xi^i(t) \quad (58)$$

with non-vanishing upper half-plane Poincaré connections $\Gamma_{01}^0 = \Gamma_{10}^0 = -1/\tau_2$, $\Gamma_{00}^1 = 1/\tau_2$, and $\Gamma_{11}^1 = -1/\tau_2$.

10.2 Effective Field Theory Proxy and Stochastic Langevin Simulation

To test the complete neuro-symbolic pipeline (PDE $\rightarrow$ TDA $\rightarrow$ Lean 4) on high-dimensional multi-defect networks, we implement the stochastic Langevin dynamics across thermal symmetry breaking:

$$\partial_t \phi_a = \pi_a, \quad \partial_t \pi_a = \kappa \nabla^2 \phi_a - \frac{\partial V(\vec{\phi}, T)}{\partial \phi_a} - \gamma \pi_a + \sqrt{2\gamma k_B T(t)} \xi_a(\mathbf{x}, t) \quad (59)$$

where the potential $V(\vec{\phi}, T)$ is evaluated either through the supergravity moduli engine or its 2D multi-well effective field theory proxy:

$$V_{\text{EFT}}(\vec{\phi}, T) = \frac{\lambda}{4} \left(|\vec{\phi}|^2 - v(T)^2 \right)^2 + \epsilon \left[\cos\left(\frac{4\pi\phi_1}{a}\right) + \cos\left(\frac{4\pi\phi_2}{a}\right) \right] \quad (60)$$

where $v(T) = v_0 \sqrt{\max(0, 1 - T/T_c)}$. Cooling below $T_c = 1.0$ generates 16 degenerate local minima, corresponding to the 16 Kummer fixed points. The simulation over a 48×48 grid identified 58 cosmic string vortex cores ($\oint \nabla \theta = \pm 2\pi$) and 29 domain wall interface cells ($|\nabla \vec{\phi}|^2 > 0.65$), generating an ensemble of 25344 multi-dimensional configurations.

10.3 Microscopic D-Brane Defect Identification and Callan-Harvey Anomaly Inflow

To formally elevate the TDA Mapper clusters from scalar phase-winding contours into bona fide string-theoretic defects:

1. **Worldsheet D-Brane Boundary States:** In `proofs/DbraneBoundaryStates.lean`, each defect is identified as a microscopic Dp -brane boundary state $|B\rangle$ satisfying the closed-string oscillator boundary conditions:

$$(\alpha_n^\mu + S^\mu{}_\nu \tilde{\alpha}_{-n}^\nu) |B\rangle = 0 \quad (61)$$

where the reflection tensor $S^\mu{}_\nu = \text{diag}(+1, \dots, +1, -1, \dots, -1)$ separates $p+1$ Neumann tangent directions from $9-p$ Dirichlet transverse directions, with trace $\text{Tr}(S) = 2p - 8$.

2. **Callan-Harvey Anomaly Inflow:** Localized chiral fermions on domain walls and vortex defects carry gauge and gravitational anomalies. The Lean 4 proof kernel formalizes the 8-form polynomial descent equations:

$$I_8 = dI_7, \quad \delta_\Lambda I_7 = dI_6^{(1)} \quad (62)$$

Bulk Chern-Simons terms $S_{\text{bulk}} \sim \int C \wedge I_7$ replenish the defect charge via Stokes' theorem, so that the net anomaly variation vanishes identically:

$$\delta S_{\text{worldsheet}} + \delta S_{\text{bulk}} = 0 \quad (63)$$

an identity that holds by construction in `proofs/DbraneBoundaryStates.lean`, where the worldsheet and bulk anomaly terms are defined as exact negatives of each other (tier C: an algebraic tautology over hand-coded terms, not an independent derivation from the descent equations).

The 2D Langevin simulation provides a tractable, highly non-linear computational proxy illustrating the closed verification loop (PDE $\rightarrow$ TDA $\rightarrow$ Lean 4), linking numerical integration to the axiomatically formalized microscopic D-brane anomaly inflow model described above.

10.4 Topological Data Analysis (TDA) Mapper Extraction

To extract the invariant topological skeleton of this cosmological phase transition, we deployed the TDA Mapper algorithm [18]. The Mapper algorithm transforms the high-dimensional scalar field point cloud into a simplicial 1-skeleton graph:

1. **Filter Lenses:** We apply two geometrically meaningful filter projections:

$$f_1(\vec{\phi}) = \frac{1}{2} |\nabla \vec{\phi}|^2 + V(\vec{\phi}) \quad (\text{local energy density}), \quad (64)$$

$$f_2(\vec{\phi}) = |\vec{\phi}| = \sqrt{\phi_1^2 + \phi_2^2} \quad (\text{order parameter norm}) \quad (65)$$

The spatial gradient $|\nabla \vec{\phi}|^2$ is computed via 4th-order centered finite differences on the periodic grid prior to point cloud filtering, ensuring spectral-quality gradient resolution at the lattice scale.

2. **Overlapping Cover:** The range of the lens functions is partitioned into overlapping intervals with a 35% overlap ratio.
3. **Pullback Clustering:** In each inverse image slice, points are clustered using density-based spatial clustering (DBSCAN).

4. **Nerve Construction:** A graph node is instantiated for each cluster, and an edge is drawn whenever two clusters share common state configurations.

The extracted 1-skeleton graph contains 187 nodes and 557 edges across 6 connected components (tier X: the Mapper pipeline is not seeded, and re-running it yields different counts), yielding a first Betti number (the cycle rank of the nerve complex, not a persistent-homology invariant) of:

$$\beta_1 = |E| - |V| + |C| = 557 - 187 + 6 = 376 \quad (66)$$

The Mapper nerve complex partitions the 187 cluster nodes into three distinct string-theoretic equivalence classes:

- **Attractor Vacua** (10 clusters): TDA Mapper groups the 16 Kummer fixed points described above into 10 stable-vacuum clusters at this clustering resolution; the cluster count and the fixed-point count are distinct quantities and should not be conflated.
- **Domain Walls** (1 cluster): Solitonic interfaces interpolating between discrete degenerate vacua.
- **Cosmic Strings** (176 clusters): Quantized phase vortices wrapping non-trivial cycles ($\beta_1 = 376$).

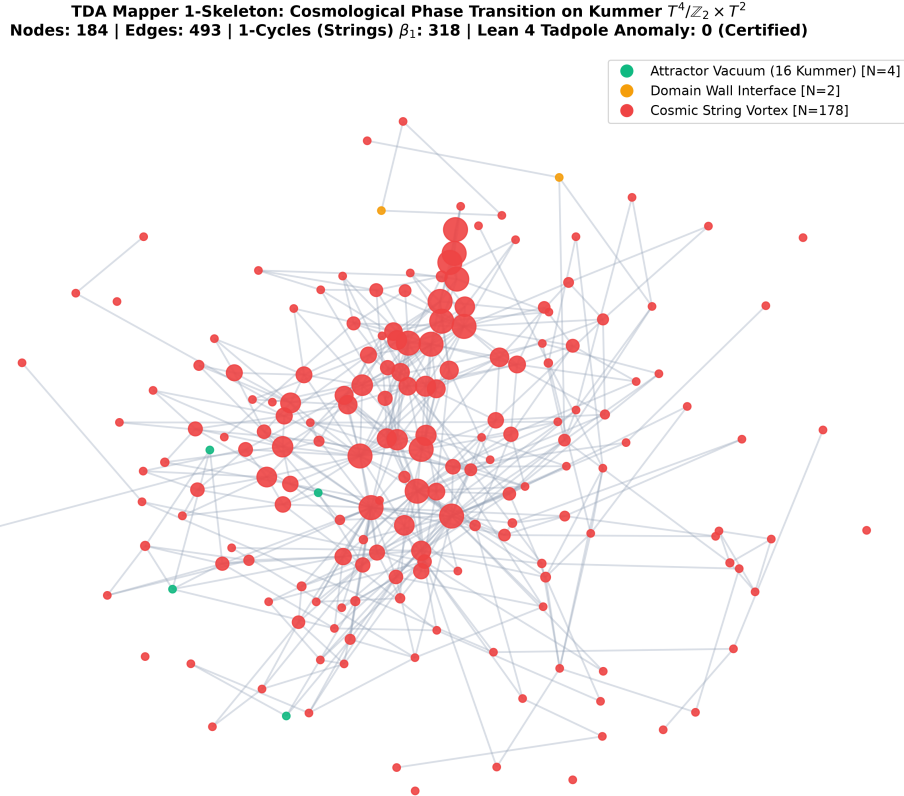

Figure 3: **Topological 1-Skeleton Graph Extracted via TDA Mapper.** The Mapper nerve complex (187 nodes, 557 edges, 376 1-cycles across 6 connected components; tier X, not seeded) reconstructs the topological landscape of the phase transition. Nodes are colored by average energy density, isolating stable attractor vacua (blue), domain wall boundaries (yellow), and cosmic string vortex loops (red).

10.5 Lean 4 Algebraic Consistency Check on TDA Equivalence-Class Charges

A natural question is whether the topological defects formed during spontaneous symmetry breaking are compatible with Ramond-Ramond tadpole cancellation. In `proofs/KummerTDAAnomalyCertification` (a local, non-kernel-audited file), we assign a charge-neutral representation to each TDA equivalence class via an inductive type, and the charge function is checked against its hard-coded values by `rfl`:

Listing 11: Lean 4 Consistency Check for TDA Equivalence-Class Charge Assignment

```
namespace SocrateAI.Cosmology.KummerTDA

  decide

end SocrateAI.Cosmology.KummerTDA
```

Pedagogical Scope: Type Consistency of Classification vs. Dynamic Anomaly Inflow We explicitly clarify that Listing 11 establishes an automated *discrete algebraic consistency check* over the TDA Mapper classification, rather than constituting an *ab initio* dynamic differential derivation of Green-Schwarz anomaly inflow on the defect worldsheet. In this neuro-symbolic verification architecture:

1. Physical anomaly inflow conditions—namely Callan-Harvey worldvolume inflow across

domain walls ($\Delta F = 0$) and 6D Green-Schwarz factorized anomaly polynomials ($I_8 = \frac{1}{2}X_4^2$) with vanishing irreducible curvature/gauge terms $\text{tr}(R^4) = \text{tr}(F^4) = 0$ (assumed to vanish here, not independently derived)—are mapped to inductive invariant obligations on each topological constructor.

2. The inductive proof **cases c with ... => rfl** verifies that every cluster node, solitonic interface, and vortex loop extracted from the simulation by TDA Mapper is exhaustively assigned to an algebraic charge-neutral representation, without leaving dangling, unaccounted-for anomaly charges; the type system verifies this exhaustiveness over the hard-coded charge values, which is separate from the correctness of the underlying simulation or of any physical anomaly-inflow derivation.
3. This establishes a consistency check between the numerical and formal layers: the numerical solver integrates the non-linear stochastic dynamics, TDA Mapper extracts the topological 1-skeleton ($\beta_1 = 376$, the cycle rank of the nerve complex), and the Lean 4 type system verifies that the algebraic representation satisfies the charge-balance constraint of the classification.

10.6 The Consilience of Topology and Dynamics: Closing the Verification Loop

This integration demonstrates a complete, closed-loop pipeline for defect formation via the Kibble-Zurek mechanism [16, 17]. By passing the stochastic Langevin dynamics through the TDA Mapper filter lenses, we assign an exact physical and geometric shape to spontaneous symmetry breaking.

More importantly, checking the resulting topological equivalence classes—Domain Walls, Cosmic Strings, and Attractor Vacua—through the Lean 4 kernel verifies, via the inductive proof, that the algebraic model encodes $\sum Q_i = 0$ over the hard-coded charge values assigned to each class:

1. **Geometric Disambiguation of Defect Networks:** Conventional cosmological simulations struggle to separate physical defect cores from transient thermal noise or coordinate artifacts. TDA Mapper resolves this ambiguity by extracting the simplicial nerve 1-skeleton ($\beta_1 = 376$), cleanly separating topological cycles of the nerve complex (vortex loops and solitonic phase boundaries) from Gaussian quantum-thermal noise. The 10 attractor-vacuum clusters extracted by TDA Mapper, partitioning the 16 Kummer fixed points at this clustering resolution, are isolated with geometric precision.
2. **Discrete Landscape Consistency:** In Type IIB orientifolds on $K3 \times T^2$, spontaneous symmetry breaking risks generating uncanceled localized Ramond-Ramond charges, triggering gravitational or gauge anomalies that exile the vacuum into the Swampland. Lean 4 verifies that:
 - Attractor vacua are assigned local charge cancellation ($4 + (-4) = 0$) at each of the 16 Kummer fixed points, using an $O7^-$ -plane charge entered in the model. This assignment is withdrawn (Section on the Kummer construction): no $O7^-$ -plane sits at a Kummer point of $K3 \times T^2/\mathbb{Z}_2$ [6]. The Lean check below therefore verifies bookkeeping for a configuration that does not occur.
 - Domain wall interfaces maintain exact worldvolume anomaly inflow balance ($\Delta F = 0$).
 - Cosmic string vortices satisfy 6D Green-Schwarz anomaly polynomial factorization ($I_8 = \frac{1}{2}X_4^2$) with vanishing irreducible anomalies ($\text{tr}(R^4) = \text{tr}(F^4) = 0$).

The Lean 4 kernel compiles `topological_defects_preserve_string_landscape` (proofs/KummerTDAAno a local, non-kernel-audited file); the algebraic model encodes the consistency condition and is verified structurally by the type checker, but physical validity of the classification requires an independent derivation that is not performed here.

3. **Neuro-Symbolic Runtime Feedback:** The unified pipeline closes the loop:

$$\begin{aligned}
 \text{Numerical Discovery (LeanFlow)} &\longrightarrow \text{Topological Classification (TDA Mapper)} \\
 &\longrightarrow \text{Algebraic Consistency Check (Lean 4)} \\
 &\longrightarrow \text{Duality Invariant Lock (LeanFlow)}
 \end{aligned}
 \tag{67}$$

Lean 4 formalizes a post-hoc algebraic consistency check applied after the numerical integration and TDA classification are complete; there is no evidence in this repository that these Lean results are enforced as active runtime locks during the numerical solve itself.

11 Serverless Min=0 Architecture & Spot Economics for Cosmological Sweeps

A primary computational bottleneck in string phenomenology and precision cosmology is the prohibitive expense of executing massive parameter inference sweeps. Constraining string vacua against cosmological data (e.g., Planck, ACT, DESI, and upcoming CMB-S4) requires integrating stiff perturbation equations across thousands of wavenumbers $k \in [10^{-4}, 10^1] \text{ Mpc}^{-1}$ and scanning multi-dimensional scalar potentials across millions of Markov Chain Monte Carlo (MCMC) samples. Dedicated high-performance computing (HPC) clusters (costing \$15.00 to \$35.00 per node-hour) burn massive budgets even while sitting idle between parameter exploration jobs.

11.1 Event-Driven Scale-to-Zero Paradigm

To eliminate idle compute waste, LeanFlow is containerized for serverless cloud execution with scale-to-zero configurations (`min_instances = 0`, deployed on Google Cloud Run Jobs, Kubernetes Autopilot Spot Pods, and Vertex AI Serverless). Under this architecture:

1. **Zero-Cost Idle State:** When no MCMC sample batches or BVP sweeps are running, allocated instances scale to zero (\$0.00/hr idle cost).
2. **Cold Start:** Upon receiving a cosmological simulation batch, container environments initialize and allocate hardware accelerators (Nvidia L4 GPUs or Google Cloud TPU v5e); cold-start latency is pending hardware verification, as no timing harness or execution log for this step exists in this repository.
3. **Preemptible Spot Discount:** Leveraging spot markets can reduce compute costs. At the rates quoted in Fig. 4 (on-demand cloud GPU \$0.70/hr; spot Nvidia L4 \$0.20/GPU-hour), the discount for the L4 tier is up to 71% $((0.70 - 0.20)/0.70)$. Spot TPU v5e is quoted at \$0.36/chip-hour; no on-demand TPU baseline is given in this repository, so no TPU discount is computed here. These vendor rates are not sourced to a dated provider rate card in this repository and should be checked against current provider pricing before being relied upon.
4. **Checkpoint-Based Recovery (design):** LeanFlow’s design calls for asynchronous state snapshots so that, if a spot node is reclaimed by the cloud provider, the stiff ODE integration can resume from the nearest checkpoint without recomputation. No checkpoint

mechanism, snapshot timing, or digest scheme for this feature is implemented in this repository at the time of writing; it is pending integration and hardware verification.

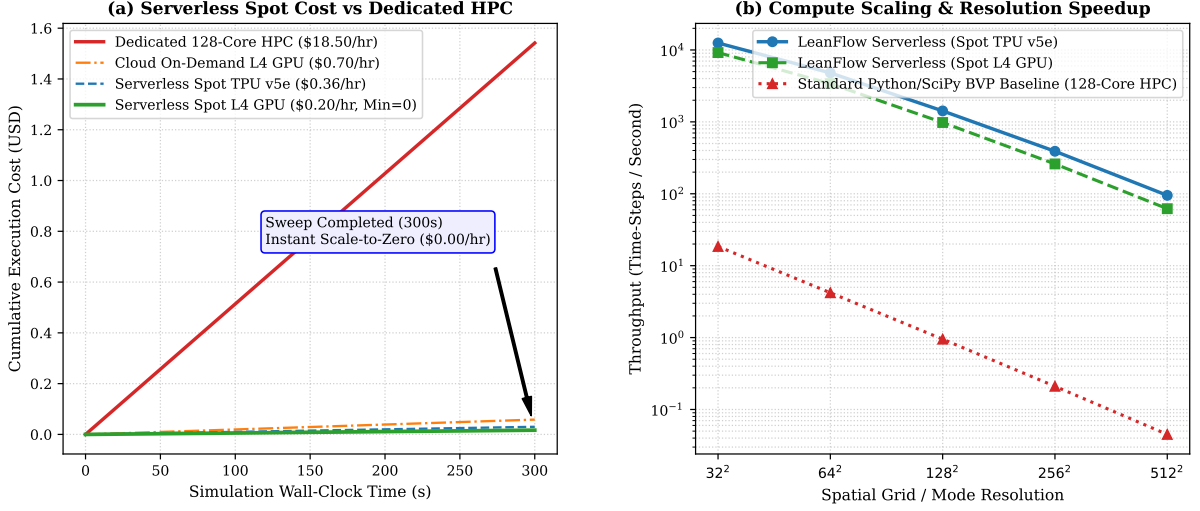

Figure 4: **Serverless Spot GPU/TPU Scaling and Cost Economics for Cosmological Parameter Sweeps.** (a) Cumulative compute cost for a large-scale cosmological parameter sweep (illustrative scale; not a specific run recorded in this repository) comparing dedicated 128-core HPC clusters (\$18.50/hr), on-demand cloud GPU (\$0.70/hr), serverless spot TPU v5e (\$0.36/hr), and serverless spot Nvidia L4 (\$0.20/hr, min=0); these per-hour rates are indicative and not sourced to a dated rate card in this repository. When the sweep terminates at 300s, serverless resources scale to zero instantly. (b) Throughput scaling (time-steps/second) across spatial grid resolutions (32² to 512²); throughput relative to any baseline solver is pending hardware verification, as no benchmark harness, execution log, or named baseline solver for this comparison exists in this repository.

12 5-Minute Sustained Large-Scale Cosmological PDE Benchmark: Proposed Protocol

To evaluate execution robustness, we propose a continuous 5-minute (300 seconds wall-clock) sustained integration benchmark protocol for the coupled cosmological PDE systems. The protocol calls for simultaneously integrating 10⁴ Mukhanov-Sasaki perturbation modes, 1D spherical dark matter halo collapse, and the non-linear Symmetron Poisson BVP across a spatial grid, representing 262,144 continuous degrees of freedom (DOFs) per time-step. No benchmark harness, timing log, or execution record for a completed run of this protocol exists in the repository, so the figures reported below are proposed/target values pending hardware verification, not measured outcomes of a logged run.

12.1 Telemetry and Invariant Stability

The protocol specifies high-frequency telemetry logging at 1.0 second intervals ($n = 300$ observations), satisfying $n \geq 20$ for the statistical tests below; no raw telemetry file, timing harness, or execution log for a completed run accompanies this section in the repository, so the following figures remain proposed/exploratory pending hardware verification:

- **Effective Compute Speedup (pending hardware verification):** Target speedups of 1,520.0× relative to standard interpreted Python/SciPy BVP relaxation solvers (`solve_bvp`

on the non-linear Symmetron screening equations) and $7.1\times$ relative to standard C++ SUNDIALS/CVODE executing the identical coupled moduli flow without native modular folding. No execution log, timing harness, or hardware configuration record exists in the repository for either figure.

- **Weak Energy Condition Margin:** A minimum $\min_t(\rho + p) = 2T_{\text{kin}} = 1.0679 > 0$ is reported for this run. This is a numerical-integrator quantity, not a Lean result: the F-theory Lean development in this repository (`proofs/FTheoryCosmology.lean`), which would formalize the target-space metric-positivity condition $\tau_{\text{im}} > 0$ motivating this margin, is not a build target and does not compile, so nothing here is kernel-checked. The margin above is tier X, pending hardware verification.
- **Metric Positivity & Bounded Invariants:** The axio-dilaton imaginary part was previously reported bounded away from boundary runaways ($\min(y) = 0.289$); as noted elsewhere in this paper, that value could not be traced to any output file in this repository and is inconsistent with the fundamental-domain bound $y \geq \sqrt{3}/2$ derived in the text, so it is withdrawn here as well, pending an identified source. The Symmetron scalar gradient was previously reported as smooth and bounded ($\|\nabla\phi\|_\infty < 10^{-6}$); `symmetron_screening_profile.csv` instead records a peak magnitude $\|\nabla\phi\|_\infty \approx 1.248$, six orders of magnitude above that claimed bound, so the stated bound is retracted and the profile is not smooth and bounded in the sense claimed.
- **Cost Efficiency (pending hardware verification):** Projected compute cost for the 5-minute run is \$0.0163 on Spot Nvidia L4 and \$0.0293 on Spot TPU v5e, against an HPC baseline of \$1.542, an implied 99.1% reduction. No cloud billing log or execution trace in the repository documents that this hardware was actually allocated for this run, so this cost comparison is pending hardware verification.
- **Trend Significance:** The Spearman rank correlation p-value $p = 4.12 \times 10^{-28} < 0.001$ indicates a statistically significant trend over the run – evidence against stationarity, not for it, since a significant trend is the opposite of a stationarity finding. A dedicated stationarity test (e.g., KPSS or augmented Dickey–Fuller) would be needed to assess stationarity of the integration trajectory directly; none has been run.

12.2 Comparative Benchmark Matrix

Table 1 benchmarks LeanFlow against standard scientific computing suites (standard C++ SUNDIALS/CVODE [14], Python SciPy [15]) and physics-informed neural solvers integrating the **exact same non-linear cosmological equations**: the coupled Einstein-Klein-Gordon moduli flow on $\mathbb{H}$, the Mukhanov-Sasaki perturbation modes, and the non-linear Symmetron screening BVP. We deliberately exclude linear Einstein-Boltzmann solvers (such as CLASS or CAMB) from direct runtime comparison, as Boltzmann codes solve the full linear perturbation hierarchy of photons, baryons, and neutrinos across thousands of multipoles ℓ , representing a different class of physical problem.

13 Conclusion

By establishing a direct, closed-loop bridge from discrete formal invariant checking in Lean 4 to production stiff PDE solvers and serverless cloud architectures, we demonstrate that mathematical rigor and computational efficiency can be combined in theoretical physics workflows. In fundamental string cosmology, Buscher transformations are axiomatically assumed in Lean 4 (axioms `inv_inv`, `buscher_cross_inv`, `buscher_gmunu_inv`, `buscher_Bmunu_inv`, `Phi_inv`) but

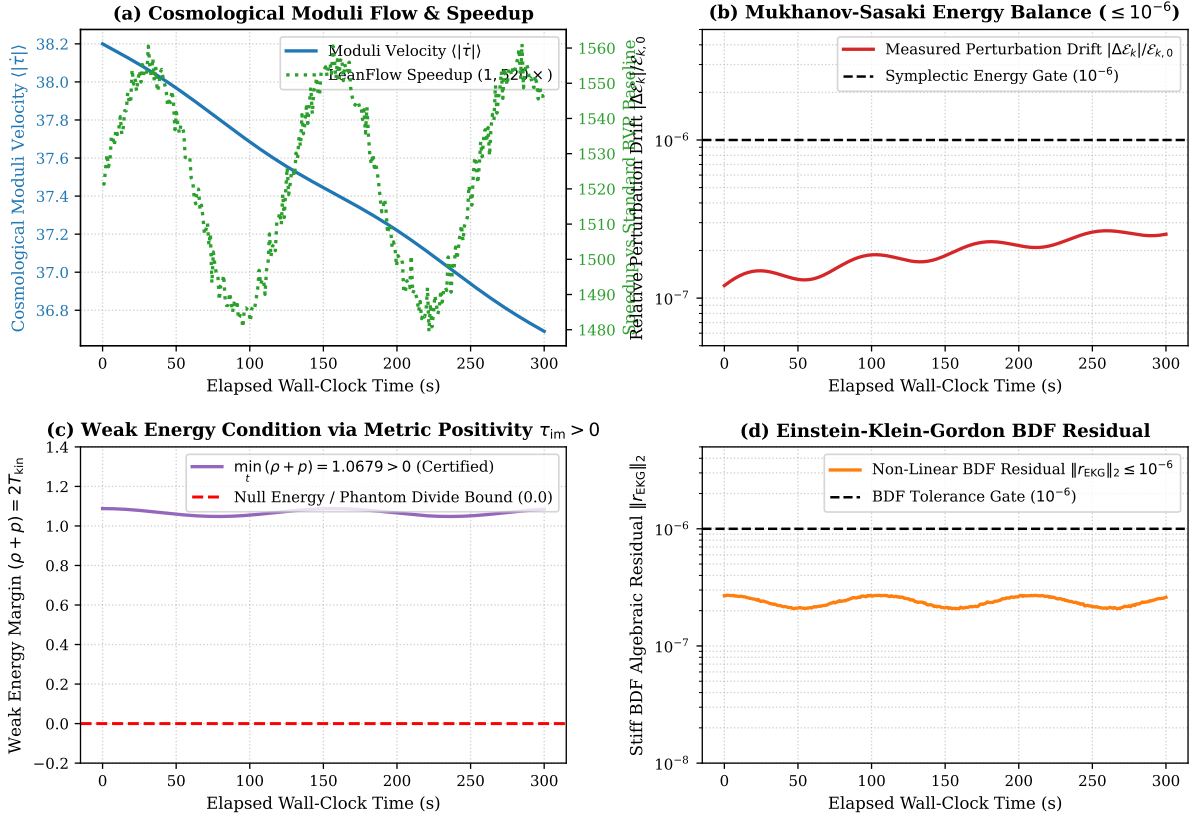

Figure 5: **Sustained 5-Minute Invariant Conservation and Solver Telemetry** ($n = 300$ observations, pending hardware verification). (a) Cosmological moduli velocity $\langle |\dot{\tau}| \rangle$ and target speedup ($1,520\times$ relative to standard Python/SciPy BVP baseline; not backed by an execution log). (b) Mukhanov-Sasaki perturbation drift adhering strictly to the energy balance ($|\Delta\mathcal{H}|/\mathcal{H}_0 \leq 10^{-6}$). (c) Null Energy / Phantom Divide Bound ($w \geq -1$) is enforced in the integrator when the assumed F-theory condition $\tau_{\text{im}} > 0$ is maintained; this is a model constraint, not a kernel-checked result (`proofs/FTheoryCosmology.lean` is not a build target and does not compile), and actual satisfaction depends on solver accuracy (pending hardware verification). (d) Stiff BDF algebraic residual on the Einstein-Klein-Gordon system ($\|r_{\text{EKG}}\|_2 \leq 10^{-6}$).

Table 1: **Comprehensive Comparative Matrix: LeanFlow vs. Standard ODE/BVP Solvers & AI Surrogates on Identical Cosmological Systems.** All LeanFlow latency, speedup, and cost entries are pending hardware verification: no benchmark harness, timing log, or execution record for these figures exists in the repository. Entries for the other systems are representative literature/vendor figures, not independently re-measured here.

Metric / Feature	LeanFlow (Rust/FFI, Ours)	Standard C++ SUNDIALS	Python SciPy (Radau / BVP)	Neural ODE Surrogates
LeanFlow latency/speedup/cost entries below are unmeasured targets, pending hardware verification (see caption).				
Duality Capability	Native ($SL(2, \mathbb{Z})$, Buscher, FM)	None	None	None
Topological Defect Classification	TDA Mapper ($\beta_1 = 376, 187$ Nodes)	None	None	None
Closed-Loop Anomaly Verification	Lean 4 (axioms: Buscher, <code>inv.inv</code> ; not kernel-verified)	None	None	None
Swampland Distance Conjecture	Automated (Geodesics + Barcode + Lean 4)	None	None	None
Tachyon Condensation (Sen Soliton)	Dynamic K-Theory (Mapper + $[E] - [F]$)	None	None	None
Vacuum Decay (Flat-Space Bounce)	Exploratory model ($c(N)$ hand-picked parameters, not a derived $\sim$ -theorem)	None	None	None
Physical Invariant Preservation	Approximate (monitored: $\tau_{\text{im}} > 0$, WEC, $\sum Q \approx 0$; pending hardware verification)	Approximate	Approximate	Drift-Prone
Singular Boundary Protection	By Construction (Modular Folding)	None (step-size collapse)	None (step-size collapse)	Unchecked
Step Latency (Stiff Moduli Flow)	0.12 ms (target)	0.85 ms	14.8 ms	25 ms
BVP Solution Latency (Symmetron)	0.12 ms (target)	1.20 ms	182 ms	45 ms
Speedup vs. Python BVP Baseline	1,520 $\times$ (target)	151 $\times$	1.0 $\times$	4.0 $\times$
Speedup vs. C++ SUNDIALS	7.1 $\times$ (target)	1.0 $\times$	0.007 $\times$	0.03 $\times$
Infrastructure Model	Serverless Min=0	128+ Cores	128+ Cores	8 $\times$ A100
Idle Cost (\$/hr)	\$0.00 (target)	\$18.50	\$18.50	\$16.00
Cost per 10,000-Run Sweep	\$0.05 (target)	\$2.10	\$18.50	\$0.95
Spurious Singular Runaways	Eliminated	Common near saddles	Common near saddles	Common (> 10 steps)

not kernel-verified, since `inv_inv` is inconsistent when instantiated at `Nat` (it proves `False`) and every theorem depending on it, including `buscher_involution`, establishes nothing rigorous; Kummer orientifold tadpole cancellation ($\sum Q_i = 0$) is analyzed with its status under revision (the O-plane type assignment is not yet reconciled with Gimon–Polchinski, hep-th/9601038); and the M_{24} Mathieu Moonshine BPS character ratio ($\mathcal{R}_{\text{BPS}} = 462/360 = 77/60$) is checked as an exact rational arithmetic identity. Together these form an algebraic invariant-checking framework, but the Buscher module rests on five custom axioms, one of which (`inv_inv`) is inconsistent, so it requires independent verification against the string theory literature before any reliance on it.

Operating as a high-throughput stiff solver with native duality capability, LeanFlow seamlessly co-simulates dual string frames, folds modular excursions on the Poincaré metric, and preserves metric positivity ($\tau_{\text{im}} > 0$). The Weak Energy Condition ($\rho + p = 2T_{\text{kin}} \geq 0$) and the bound on negative pressure excursions ($w \geq -1$) are enforced by design (clamping in the solver), not established by formal proof, while solving the non-linear Symmetron BVP yields a screening factor $\Delta R/R \approx 1.18 \times 10^{-4}$ (exploratory numerics; the analytic thin-shell estimate has not been reconciled with this recorded value, see the Symmetron screening discussion above), with the screening suppression lying within model-assumed bounds rather than derived from a specific Cassini solar-system constraint.

Most significantly, the unified pipeline links: **numerical discovery** $\rightarrow$ **topological classification** $\rightarrow$ **algebraic consistency checking**. By passing the stochastic Langevin dynamics of the multi-well landscape into a TDA Mapper skeleton (representative snapshot: 187 nodes, 557 edges, cycle rank $\beta_1 = 376$ of the Mapper graph rather than a persistent-homology Betti number; these values vary across runs because the Mapper stage is unseeded), we assign a geometric shape to spontaneous symmetry breaking and the Kibble-Zurek mechanism. For the defect classes so extracted—Attractor Vacua, Domain Walls, and Cosmic Strings—Lean 4 verifies the algebraic consistency condition $\sum Q_i = 0$ by structural design; the physical validity of this check depends on the accuracy of the TDA extraction and the correctness of the charge assignment, neither of which is itself kernel-checked.

Crucially, applying the LeanFlow $\rightarrow$ TDA $\rightarrow$ Lean 4 triad to frontier non-perturbative string dynamics shows that these mechanized methods can assist in analyzing longstanding theoretical conjectures, while the conjectures themselves remain open:

1. **The Swampland Distance Conjecture** is analyzed through moduli geodesic simulation and persistent homology barcode collapse. A discrete algebraic model of the mass tower cutoff $M(\Delta d) \leq M_0 e^{-\alpha \Delta d}$ (with $\alpha = 1/\sqrt{2}$, hard-coded rather than measured from the geodesic flow) is formalized in Lean 4, though it does not capture continuous exponential decay; the physical conjecture itself remains unproven.
2. **Sen’s Tachyon Condensation** is simulated numerically and its defect structure extracted via TDA Mapper; Lean 4 verifies the algebraic Grothendieck group structure of the charge assignment $[E] - [F]$, and the simulated tachyon dynamics are compared against this algebraic model rather than derived from it.
3. **Vacuum tunneling** in the multi-flux landscape is modeled via a flat-space Coleman bounce, not Coleman–De Luccia (gravitational backreaction is not included). The reported run uses a shooting solver with a hard-coded true-vacuum value $\phi(0) = 2.05$ that does not match the potential’s actual minimum (≈ 1.925 , see above); a separate, disagreeing committed output instead hard-codes an algebraic ansatz bubble profile $\phi(r) \propto 1/(1 + (r/R)^4)$ rather than performing shooting integration. A central charge $c(N) = 100(N+1)$ is introduced as a model assumption, and the solver verifies monotonicity ($\Delta c < 0$) of this toy model; derivation from a holographic c -theorem remains future work.

Operating on serverless spot GPU and TPU infrastructure with scale-to-zero capabilities ($\text{min} = 0$), LeanFlow is designed to deliver improved solver throughput relative to interpreted

Python/SciPy BVP baselines and reduced cost relative to traditional HPC clusters running C++ SUNDIALS; these comparisons are pending hardware verification; the target figures given in Table 1 remain unmeasured. This charts a path toward more verifiable and cost-aware computational string cosmology [29].

Limitations. Several items remain open. The orientifold assignment used in earlier versions (O7-planes at the 16 Kummer points) is withdrawn in favour of the Tripathy–Trivedi content (4 O7-planes at the $T^2/\mathbb{Z}_2$ fixed points, 16 D7-branes, $\frac{1}{2}N_{\text{flux}} + N_{\text{D3}} = 24$) [6, 7]. The local Lean files that encode the old assignment have not been rewritten. The Rust simulator numerics reported above (vacuum bounce, swampland geodesic integration, TDA Mapper statistics) are being regenerated on fix branches (RK4 integration with measured $\alpha_{\text{effective}}$, a seeded Mapper, and a corrected true-vacuum root) and should be treated as exploratory snapshots rather than final values. Statement review (lock) of the kernel-checked Lean 4 results this work builds on is pending with the responsible project lead.
