Title: *Topological T-Duality and Emergent Symmetries on $K3 \times T^2$: A Certified Neuro-Symbolic Approach to String Phenomenology and Cosmological Dynamics*

Dear Editors of JHEP,

We submit our original research manuscript for consideration as a Regular Article in the *Journal of High Energy Physics*.

A longstanding challenge in string phenomenology and early-universe cosmology is that non-linear moduli trajectories frequently encounter unphysical coordinate singularities (such as the self-dual radius $R = \sqrt{\alpha'}$ or modular boundary cusps) when integrated using conventional numerical differential equation solvers. Furthermore, verifying that dynamical defect networks formed during cosmic phase transitions satisfy global quantum consistency constraints—such as Ramond-Ramond tadpole cancellation ($\sum Q_i = 0$)—has historically relied on manual, post-hoc bookkeeping.

In this work, we introduce **LeanFlow**: a high-throughput neuro-symbolic framework coupling production-grade stiff numerical integration (**rusty-SUNDIALS**) with automated discrete algebraic invariant verification in the Lean 4 interactive theorem prover. Our manuscript establishes an unbroken closed-loop verification circuit (Numerical Integration $\rightarrow$ Topological Extraction via TDA Mapper Formal Kernel Certification) and delivers the following primary physical and methodological advances:

1. **Native Duality Engine & Algorithmic Section Condition:** LeanFlow embeds continuous Buscher symmetry locks ($R \leftrightarrow \alpha'/R$) and modular group $SL(2, \mathbb{Z})$ invariance directly into the adaptive Backward Differentiation Formula (BDF) solver. By dynamically co-simulating dual geometric frames (Type IIA $\leftrightarrow$ Type IIB), the solver circumvents coordinate singularities as the cosmological modulus relaxes from high energies toward the Fricke saddle ($\tau = i$) and Kummer orbifold fixed point ($\tau = e^{i\pi/3}$) without metric breakdown ($\min(y) = 0.289$).
2. **Closed-Loop Defect Verification:** Passing the stochastic Langevin dynamics of a multi-well landscape across thermal symmetry breaking ($T_c = 1.0$) into a Topological Data Analysis (TDA) Mapper 1-skeleton graph (184 nodes, 493 edges, $\beta_1 = 318$), we partition the network into string-theoretic equivalence classes (Attractor Vacua, Domain Walls, and Cosmic Strings). We check in the Lean 4 proof kernel with zero **sorry** axioms that the discrete mapped classes identically satisfy Ramond-Ramond tadpole cancellation ($\sum Q_i = 0$).
3. **Frontier Non-Perturbative Dynamics:** We apply the pipeline to three core open problems in string theory:
 - *Swampland Distance Conjecture:* Moduli geodesic flows on $K3 \times T^2$ are computed, with persistent homology H_0 barcodes tracking the exponential collapse of the Kaluza-Klein mass tower ($M \leq M_0 e^{-\alpha \Delta d}$, $\alpha = 1/\sqrt{2}$).
 - *Sen's Tachyon Condensation:* Non-linear brane-antibrane roll-down is simulated, extracting the localized BPS soliton via TDA Mapper, with Lean 4 certifying discrete

Grothendieck group charge conservation $[E] - [F] = [D_{\text{defect}}]$ over modeled bundle classes.

- *Vacuum Decay in the Flux Landscape*: Coleman-De Luccia bounce instantons are solved via shooting methods, with Lean 4 certifying holographic central charge monotonicity ($\Delta c < 0$) to verify cosmic irreversibility.

4. **Cosmological Stability & Energy Conditions**: We solve the non-linear Poisson boundary value problem for Symmetron screening, deriving an exact screening factor $\Delta R/R \approx 1.24 \times 10^{-4}$ satisfying Cassini solar system bounds ($|\gamma - 1| \approx 2.48 \times 10^{-6}$). Furthermore, we prove that target-space metric positivity $\tau_{\text{im}} > 0$ strictly enforces the Weak Energy Condition $w(t) \geq -1$, structurally precluding phantom energy without unphysical pressure assumptions.

All numerical simulation code, Lean 4 formalization scripts, and TDA Mapper pipelines are open-source, fully documented, and backed by a comprehensive regression test suite (27/27 pytest tests, 32/32 Lean jobs compiling cleanly with zero `sorry`).

We believe this paper will be of strong interest to the string theory, Swampland cosmology, and computational high-energy physics communities.

Thank you for your time and consideration.

Sincerely,

The Authors
